

REPORT
OF THE
INDUSTRIAL COMMISSION

ON
AGRICULTURE
AND
AGRICULTURAL LABOR,

INCLUDING TESTIMONY, WITH REVIEW AND TOPICAL DIGEST THEREOF.

VOLUME X
OF THE COMMISSION'S REPORTS.

WASHINGTON:
GOVERNMENT PRINTING OFFICE.
1901.

MEMBERS OF THE INDUSTRIAL COMMISSION.

Mr. ALBERT CLARKE, *Chairman*.

Senator BOIES PENROSE.	Mr. ANDREW L. HARRIS.
Senator STEPHEN R. MALLORY.	Mr. JOHN M. FARQUHAR.
Senator JOHN W. DANIEL.	Mr. EUGENE D. CONGER.
Senator THOMAS R. BARD.	Mr. THOMAS W. PHILLIPS.
Representative JOHN J. GARDNER.	Mr. CHARLES J. HARRIS.
Representative L. F. LIVINGSTON.	Mr. JOHN L. KENNEDY.
Representative JOHN C. BELL.	Mr. CHARLES H. LITCHMAN.
Representative THEOBALD OTJEN.	Mr. D. A. TOMPKINS.
Mr. WILLIAM LORIMER.	

E. DANA DURAND, *Secretary*.

[Extract from act of Congress of June 18, 1898, defining the duties of the Industrial Commission and showing the scope of its inquiries.]

SEC. 2. That it shall be the duty of this commission to investigate questions pertaining to immigration, to labor, to agriculture, to manufacturing, and to business, and to report to Congress and to suggest such legislation as it may deem best upon these subjects.

SEC. 3. That it shall furnish such information and suggest such laws as may be made a basis for uniform legislation by the various States of the Union, in order to harmonize conflicting interests and to be equitable to the laborer, the employer, the producer, and the consumer.

LETTER OF TRANSMITTAL

OFFICE OF THE INDUSTRIAL COMMISSION,
Washington, D. C., December 5, 1901.

To the Fifty-seventh Congress:

I have the honor to transmit herewith, on behalf of the Industrial Commission, a report to Congress on the subject of agriculture, prepared in conformity with an act of Congress of June 18, 1898. This report consists of the testimony on this subject taken before the Commission, with a review and digest thereof. The Commission has also had prepared several special reports on topics connected with agriculture, which are printed in Volume XI. The conclusions and recommendations of the Commission on this subject will be presented in its final report.

Respectfully submitted.

ALBERT CLARKE, *Chairman.*

REVIEW AND DIGEST OF EVIDENCE.

REVIEW OF THE EVIDENCE.

INTRODUCTION.

The importance of agriculture among the industries of the country is attributed in part to its fundamental character,¹ but is due also to the large number of persons engaged in agricultural employments. The agricultural population of the country doubled during the 40 years between 1850 and 1890, and at the latter date constituted more than one-third of the entire population, about 8,500,000 persons being engaged in gainful agricultural occupations and representing a total agricultural population of about 27,000,000. A little more than 60 per cent of those engaged in agriculture owned their farms, the remainder being either tenants or hired laborers.²

The wealth of the farmers, which is estimated to have been nearly one-half of the entire wealth of the country in 1860, has increased less rapidly than other forms of wealth, and in 1890 amounted to about one-fourth of the wealth of the country. In some of the Eastern States there has been an actual diminution in the number of farms.³ The value of farms was given by the Eleventh Census as a little more than \$13,000,000,000, or, including live stock and farming implements, about \$16,000,000,000.⁴

Productivity of agriculture.—Professor Bailey calls attention to a decided increase in the average productivity of farms during the past century. The average yield of wheat near Philadelphia in 1791, according to the testimony of a contemporary observer, was rather less than 8 bushels to the acre, while dairy cows averaged only 104 pounds of butter a year. A comparison of these figures with present conditions in the same locality shows an increase of more than 100 per cent in the yield of both products, and Professor Bailey's final conclusion is that the average productivity of agriculture has increased in even a greater ratio than this. He attributes the increase to the use of better tools and fertilizers, rotation of crops, and better tillage. The activity of the farmers has been stimulated both by increased competition and by more varied demand for agricultural products. On the other hand, insect pests and diseases of plants and animals have been introduced from abroad; but they are under better control than formerly.⁵ Other witnesses think it doubtful whether the product per acre has increased on the whole, in spite of the tendency toward intensive agriculture in certain lines.⁶ According to the census the aggregate value of farm products remained nearly stationary during the two decades, 1869-1889, while the value of manufactures nearly doubled during the latter of these decades; but the census is thought to show too small a product in the case of agriculture and to magnify the increase of manufactured products.⁷ Comparing 1880 with 1894, there appears to have been an increase in the aggregate production, and also in the yield per acre, but a loss in the money value of the product.⁸

GENERAL AGRICULTURAL CONDITIONS.

The testimony of different witnesses as to the general condition of agriculture shows marked differences of opinion, some complaining of depression and others testifying to increased prosperity. This conflict of testimony may perhaps be reconciled to some extent by remembering that the different witnesses speak with particular reference to their own sections of the country, and also that the standard of comparison varies. It is mainly from the Eastern and Southern States that complaints of depression have been heard, and both in the East and in the South there is evidence of an improvement of conditions during the past few years.¹ Some witnesses compare recent conditions with those of the period of high prices following the civil war,² and the discontent of farmers in certain sections is attributed to the tendency to use that era of agricultural prosperity as a standard of comparison, whereas if the comparison were made with the period preceding the war an increase of prosperity would be shown.³ A number of witnesses call attention to an increase in the usual standard of living of many farmers.⁴ Again, the testimony of Southern agriculturists varies greatly with the time at which it was given. A South Carolina cotton planter testified that he made money steadily until 1890, but after that date, in spite of fertile soils and propitious seasons, there was hardship and distress, prices had fallen, crops would not pay the expense of production, and landowners were losing their property. Cotton planters and other Southern witnesses who testified after the close of 1890, however, reflected the influence of better prices for cotton.⁵

While these conflicts of testimony may be explained to some extent by differences of time and locality, they appear to be due also in part to differences in the point of view. Thus, a series of questions as to the existence and causes of agricultural decline sent out by Professor Bailey to representative New York farmers brought out decided differences of opinion. Out of 20 farmers who replied to the questions, six affirmed the existence of a general agricultural depression. The decline in the selling value of farm land is frequently taken as an evidence of agricultural depression in the East, but it is pointed out that from the standpoint of intending purchasers of farms a low purchase price makes possible a good rate of profit and comparative ease in paying for the farms bought after the decline in price.⁶

Causes of agricultural depression.—The cause most often assigned for the depression of agriculture in the Eastern States is the increased production due to the opening of Western lands in advance of the natural demand, especially through the agency of liberal land laws and grants of land in aid of railroad construction. The competition of the West has been rendered especially severe by the policy of the railroads in making freight rates relatively low for long distances. The old staple products having thus become unprofitable in the East, it has been necessary for farmers to change their methods and vary the character of their crops, taking up especially the culture of products which are not easily transported long distances. Thus truck farming has largely superseded cereal growing along the Atlantic coast, but farmers in the North Atlantic States now complain of the severe competition of States farther south in this industry, and much the same may be said of fruit growing. Even so perishable a commodity as milk is trans-

⁶ Bailey, 1006-1010; Ketchum, 134-136.

ported much longer distances than formerly since the introduction of refrigerator cars.¹

Another cause which several witnesses assign for the unsatisfactory condition of agriculture in some parts of the country is the conservatism of the farmers, their lack of quick adjustment to changed conditions, and lack of effective business planning and management. The farmers as a class have not kept up with the times, but have raised the same crops year after year without regard to changes in supply and demand.² This undue conservatism and lack of managing ability among farmers is especially emphasized with reference to the Southern States, and is given as an explanation of the too exclusive attention to cotton production prevailing there.

Another cause assigned for agricultural depression in the South is the scarcity of money, the difficulty of borrowing on real estate security, and the consequent high rates of interest.³ It seems to be possible, however, to borrow money in the South at somewhat lower rates of interest than formerly.⁴ The decline in the price of cotton is of course an important element in the depression of agriculture in the South.⁵ The inefficiency of negro labor is assigned as another cause.⁶ On the other hand, it is affirmed that there is too much good and cheap labor in the South. An abundance of cheap labor is said to be unfavorable to the success of agriculture, because it results in planting too large an acreage and in neglect of personal attention by the planter.⁷

Against the charge that farmers are unduly conservative is put the counter-charge that they turn from one crop to another without sufficient regard to the suitability of the climate and soil, or to the conditions of the market.⁸

Professor Bailey considers the lack of good farming the fundamental cause of most of the agricultural unrest. By this he appears to mean not only exhaustion of the soil by injudicious methods of culture and failure to adopt sufficiently intensive methods of cultivation, but also the general lack of executive ability which makes it difficult for the farmer to direct the labor of others with profitable results.⁹

Diminution of profits.—The preponderance of testimony is to the effect that capital employed in agriculture yields a lower rate of profit than it did 30 or 40 years ago,¹⁰ but it is pointed out that profits in all other industries have been falling, together with the rate of interest, and the number of men who are seeking and acquiring farms is cited as evidence that relatively there is more profit in farming than ever before. To those who understand farming the farm is said to be the best place to make money.¹¹ It is also pointed out that in calculating the rate of profit much depends upon the basis of calculation. Much land that was bought at very low prices 40 years ago is now worth many times the original price. If the rate of profit is calculated upon the present selling value of the land it will, of course, be much lower than if calculated upon the price which was paid for the land while it was cheap. The actual profit of the farmer, therefore, depends upon whether the land was bought at a low or a high price.¹² Again, where land was bought at inflated prices and has since fallen in value, it may fail to pay a fair profit upon the actual purchase price and yet afford a reasonable prospect of profit to a new purchaser who is able to secure it at a lower price. The agricultural depression which results in lower selling values of land thus becomes an opportunity to the

prospective buyer of farms, and makes it easier for farm laborers and tenants to rise to the position of independent proprietors.¹

Prices.—The general tendency of prices of farm products during the latter part of the nineteenth century was downward. Meat, poultry, and dairy products seem to form an exception to the rule,² but a Southern witness speaks of a marked decline even in the price of meat.³ While the apparent decline was due partly to the inflation of the currency during and after the civil war,⁴ it is stated (with special reference to South Carolina) that it now takes twice as much of the products of labor to pay taxes, debts, and fixed charges as it did in 1873.⁵ It is claimed by some witnesses that the decline in the prices of farm products is fully offset by the cheapening of manufactured goods and supplies consumed by the farmer, and by improved and cheapened methods of production.⁶ Since about the middle of the last decade, when prices reached a very low point, there has been a reaction. Attention is called especially to a steadier demand and an upward tendency in the prices of meat.⁶

The cause of low prices for agricultural products is identified with the principal cause assigned for agricultural depression in general: that is to say, the rapid development of the West, which led to an overproduction of staple crops.⁷ It is pointed out that there has been no great decline in prices except in the case of those crops which have been overproduced in comparison with the increase of population. Inasmuch as the demand for food products remains nearly constant, assuming the population to remain the same, even a slight increase in the production may result in a material lowering of prices. The law governing prices is said to be that the diminution of price is in proportion to the square of the increase in the product per capita.⁸

The recent reaction from the tendency toward lower prices has extended to many manufactured articles, as well as to agricultural products. Specific complaints are made of the increase of prices of iron and steel articles, especially wire fencing and nails, also of lumber and other building materials. The increase in prices is attributed partly to natural causes and partly to the influence of large industrial combinations.⁹ In the case of agricultural machinery, the testimony shows a decided lowering of prices since 1870. A self-binder, for example, which formerly cost from \$300 to \$400, is now obtainable for about \$125. The high price of these machines when first introduced is explained by the necessity of sending a mechanic with each machine to show the purchaser how to use it, an expense no longer necessary after farmers have become generally familiar with the use of such machinery.¹⁰ Plows also are now obtainable for less than half as much as in 1870, besides being of better quality.¹¹ On the other hand, within a few years the price of plows and other steel implements has risen somewhat, and it is said that some implements have been sold in Europe and in Canada at considerably lower prices than in this country.¹²

Prices of land.—The prices of agricultural land in the Eastern States have generally fallen, in some cases to about 50 per cent of the figures asked during the time of high prices. There is said to have been also a general decline in the price of land along the Mississippi River.¹³ Figures given for Pennsylvania show an increase in the average price of farm lands between 1859 and 1879 (the high prices preceding the latter year being explained by the inflated currency), but a drop by 1889 to a lower price than that of 30 years previous.¹⁴ While one observer says

there has been a slight increase in the value of farm lands in New York State within the past few years, this is denied by another citizen and official of that State.¹

Since any cause which tends to diminish the profits of agriculture will have an effect upon the price of farms,² the causes assigned for low prices of farm products, and for agricultural depression in general, may be taken as causes of the decline in the price of farm land: but special stress is laid upon the effect of the ease with which farms have been obtained on the public domain, and of the acceleration of Western development by land grants to railroads and by discriminating freight rates.³ It is also pointed out that owing to the growth of manufacturing and commercial interests in the United States, capital finds a more remunerative field of investment in those directions than in agriculture.⁴ One of the chief causes for the decline in value of land in the Eastern States appears to be a loss of fertility in the land itself, due, perhaps, to careless farming,⁵ though on the other hand there is evidence showing that the rapid exhaustion of soils in the Eastern and Southern States is in reality not the exhaustion of the soil in a chemical sense (for the elements of plant food remain present in abundance), but is to be explained rather by the failure of the farmers to make the most of the natural resources of the land; and this, in turn, is explained partly by social rather than physical causes.⁶

In the Central and Western States there appears to be no such marked decline in farm values as in the East, and so far as there has been an apparent decline it is explained in great part by the inflated currency in which values were reckoned at the close of the civil war,⁷ and partly, as in the East, by the exhaustion of the soil and the neglect of buildings and other improvements.⁸ In the Northwest lands seem to have been increasing in value, and in some localities to a very marked degree.⁹

It is somewhat difficult to compare the prices of land in the South with the prices prevailing before the war, because lands were not then generally for sale.¹⁰ There seems to be no doubt, however, that there has been a general decline in the money price of Southern lands; but this is explained largely or wholly by the increased purchasing power of money, and the Kentucky Commissioner of Agriculture is of the opinion that land in that State would bring less in gold 25 years ago than at present.¹¹ It is questioned whether the South has suffered more than other sections east of the Mississippi, so far as the price of land is concerned. While cotton land suffered materially for some time after the war, during the past few years there appears to have been a reaction in the direction of better prices.¹² So far as there has been a decline in the price of land in the South, it is attributed to the decline in the prices of agricultural products and to the insufficient population. It is said that white labor is kept away from the South to some extent by the presence of negroes.¹³

About 1890 California lands showed the effect of the high prices of fruit in an increase of values which could scarcely be expected to be permanent. Land can now be obtained at about one-third, or even less, of the prices prevailing at that time. Land suitable for cereals may be obtained for very much less than the price of fruit lands, and grazing lands can of course be had at still lower figures. It is said that there was never more favorable time than the present to secure homes in California at reasonable prices.¹⁴

Agricultural implements.—The introduction of improved agricultural implements and machinery during the latter half of the nineteenth century was a development of such importance as to amount to an industrial revolution in agriculture. The most conspicuous effect of the use of improved machinery is the reduction in the cost of producing farm products.¹ Figures are given by one or two witnesses showing in a striking manner a remarkable reduction in the time required to perform certain agricultural operations.² One obvious result of the use of improved implements is the lessening of the number of laborers required on a farm;³ but machinery seems to have brought with it a more intensive system of agriculture and an extension of agricultural operations, so that in some localities, at any rate, the number of laborers employed has not been diminished.⁴ It is also stated that improvements in agricultural machinery have brought about diversification of crops,⁵ and that by opening up new avenues of industry it has given employment to those formerly engaged in hand labor, and so, on the whole, improved the condition of labor.⁶ One witness estimates that the cost of production of a crop is approximately the same as about 40 years ago, notwithstanding the use of improved machinery, because of the necessity of using commercial fertilizers and the increased cost of farm labor.⁷ Moreover, it is charged against agricultural machinery that it has made the work of agricultural laborers less regular than formerly, the work being hurried through as rapidly as possible.⁸

Machinery is also charged with having helped to reduce the price of grain by making it possible to open up large areas of prairie land, and a good many farmers are said to have been ruined by buying machinery which they did not need and could not pay for.⁹

There is no doubt, however, that improvements in machinery have lessened the drudgery of farm labor and made the work less severe and fatiguing.¹⁰

One important effect of improved machinery is doubtless the educational effect upon those who use it. While there is perhaps less manual skill of certain kinds among farm laborers than formerly, as there is no longer any demand for expert cradlers, expert binders, etc.,¹¹ on the whole the effect of the use of machinery has been to raise the intelligence and skill required on the part of those who use it, whether hired laborers or farm owners, and this is said to have resulted in improving the intellectual status of the American farmer. The less general use of improved machinery in the South than in other sections is cited in partial explanation of the slow rate of agricultural progress in that part of the country,¹² and is itself explained by the lack of mechanical skill on the part of the negroes, and by the cheapness of labor, which makes it more economical to employ hand labor in many operations which could be more cheaply done by machinery where labor is more expensive.¹³ Various kinds of agricultural machinery are being gradually introduced in the South, however, notably in the cultivation of sugar cane and rice in Louisiana.¹⁴ Where improved machinery is used in the South it is said to increase the wages of those who are able to handle it.¹⁵

Mr. Hammond, of South Carolina, complains of a stagnation in the mechanics of agriculture. The period of great development in agriculture, he says, was the golden decade of 1850-1860, during which the increase in the value of farm implements and machinery was 62 per cent. a rate of increase which has not been maintained since that time. Mr. Hammond attributes the decline in the rate of increase

to the consolidation of farm-implement firms in large combinations, which acquire possession of new patents, and in some cases suppress them rather than incur the expense of adopting new models.¹

FARM TENURES.

Ownership.—While many statements are made by various witnesses concerning the ownership of farms in different sections of the country, the testimony on this subject does not rest upon a very satisfactory statistical basis for the most part. One witness makes the statement that a young man who starts with nothing as a farm laborer can not generally acquire a farm of his own and get out of debt within his natural life, even in the Northwest.² On the other hand, it is stated that a larger proportion of the immigrants to this country have become farm owners in recent years than before the enactment of the liberal land laws.³ There is some evidence that farm laborers do frequently rise in the course of time to the position of proprietors,⁴ and also that farms are quite commonly purchased as investments by persons in other occupations.⁵

Mortgages.—The mortgage indebtedness of farmers seems to have been reduced, in some localities at least, during the past decade. This appears to be true of the Dakotas⁶ and Alabama.⁷ On the other hand, considerable land has been forfeited to mortgage companies and other creditors, even in South Dakota,⁸ and also in the East⁹ and South.¹⁰ Where this is the case the mortgagers are becoming tenants or are drawn into the towns and cities. The existence of mortgages on farm property need not necessarily be taken as an evidence of adversity, because of the general custom of buying farms on credit and giving a mortgage for part of the purchasing price. It is even stated that many of the farmers of North Dakota who might pay off their mortgages prefer to keep their original purchase incumbered in order to have money to buy additional land. The so-called crop-payment plan of reducing indebtedness is frequently resorted to in that locality and is pronounced to be an excellent plan. Under this arrangement the purchaser binds himself to pay each year one-half the grain he raises.¹¹

Tenancy.—The farm tenancy existing in the United States is distinguished from a system of absentee landlordism under which lands are leased to a permanent tenant class. Fear of the development of such a system has led to statutory provisions to prevent it. In New York State farms were formerly leased for a period of time as long as 100 years, but dissatisfaction with this custom led to a provision in the State constitution of 1846 forbidding the leasing of farm lands for more than 12 years.¹²

Farm tenancy is considered from a number of different points of view. There is some testimony to the effect that capitalists, foreseeing that agricultural land is likely to increase in value, are buying up small farms, or acquiring them through the foreclosure of mortgages, and putting on tenants. This practice is said to be growing in the richer portions of Minnesota, the Dakotas, and other States.¹³ Through the foreclosure of mortgages many who formerly owned farms have become tenants, and it is predicted that the Twelfth Census will show more tenant farmers than ever before.¹⁴ From another point of view, tenancy is considered as an upward step on the part of those who were formerly farm laborers, enabling them to go into business for themselves with but little capital.¹⁵ Some tenants

who might buy land seem to prefer to remain tenants. Thus in the Yazoo Basin some tenants pay as much as \$6,500 rent a year, and in some cases subrent to smaller tenants.¹

Of the two main kinds of tenancy, cash rentals and crop sharing, the former seems to be on the increase in some parts of the country, both North and South.² Most of the testimony concerning the conditions of tenancy, however, has reference to crop-sharing contracts. The share of the crop which is paid to the landowner under these contracts varies apparently from one-fifth to two-thirds, this wide variation being due mainly to varying circumstances. The fertility of the soil is an element sometimes considered in fixing the terms of the lease, the owner of a rich soil expecting a greater share of the product than one whose soil is comparatively barren. A more important cause of the variation, however, is the varying practice of landlords in furnishing utensils and supplies as well as the land itself. In many cases where the tenant has little or no capital the landlord furnishes the implements, live stock, seed (or in other cases half the seed), and half the commercial fertilizer, or a share of the fertilizer equal to his share of the crop. The most common arrangement seems to be that for the land alone the owner shall receive one-third of the crop, while if the equipment is furnished also and the tenant's contribution to the partnership is limited to little or nothing beyond the labor required the crop is divided equally. In some parts of the South these two plans are distinguished by distinct names. A tenant whose landlord furnishes the land and utensils and pays for the fertilizers in proportion to his share of the crop is called a "cropper," while a tenant who furnishes his stock is called a "renter." Under either plan it is common for the landlord to furnish the tenant a house, an acre or so for garden purposes, and firewood.³ The house and garden are commonly provided in the North also, but there the rental value of these premises is perhaps more apt to be considered than in the South, in fixing the rent or the terms of the contract, and the tenant is sometimes required to pay for firewood.⁴ In the South the conditions of crop sharing have been so far elaborated that a distinction is frequently made between different crops in determining the share which is to go to the landlord. Thus in Georgia the landlord receives one-fourth of the cotton, one-third of the corn, and one-half of the small grain,⁵ and in South Carolina, where payment of rent in kind is said to be passing away, the former practice was to pay the landlord one-fourth of the corn and one-fifth of the cotton. This practice is giving way to cash rents and to the system of cropping on halves, the equipment and half the fertilizer being furnished by the landlord, who also pays half the cost of ginning and marketing the cotton.⁶ In Kentucky the landlord receives one-half the corn, but in the case of tobacco one-half the net proceeds after expenses are deducted; and in the case of corn land the tenant is not usually furnished with a house.⁷ Cotton land is sometimes rented for a stipulated amount of cotton, a system which has features both of crop sharing and of fixed rental. Thus in Georgia a tenant pays from 500 to 1,000 pounds of cotton for as much land as he can work with one mule.⁸ In Tennessee about 10 acres of land, more or less, rent for a bale of cotton.⁹ In Louisiana croppers divide the cotton equally with the landlords, who furnish the mules and their feed, while renters pay a stipulated rent, either in money, in cotton, or in cotton per acre.¹⁰

The system of cash rental is sometimes found to work more satisfactorily than crop sharing,¹¹ but, on the other hand, it is thought that a tenant who rents on

shares is more apt to keep up the fertility of the soil, at least where the landlord bears part of the expense of fertilizers and supervises the work of the tenant to some extent.¹ There is some testimony to the effect that renting land on shares is more profitable to the landlord than renting for a cash rent or a stipulated amount of cotton.² Mr. Greeley, of South Dakota, while emphasizing the advantages of crop sharing, advises paying the tenant partly in cash, in order that he may feel sure of something in case of failure of the crop. Mr. Greeley finds it more profitable, in the case of sheep husbandry at least, to give tenants two-thirds than to give them only one-half, because the tenant's self-interest is aroused by the larger proportion.³

Some of the advantages and disadvantages of tenancy in general are brought out in what Dr. Crowell says of the English tenant farmer, who has his capital free to use in cultivation, but, on the other hand, is obliged to sow the crop prescribed in the lease, although there may be little sale for it.⁴ It is said that tenancy reduces the average yield,⁵ but the principal disadvantage of the system from the landlord's standpoint is the impoverishment of the soil, which is apt to receive less attention and care from a tenant than from an owner.⁶ In Massachusetts attempts are made to overcome this disadvantage by prescribing in the contract that a tenant must fertilize the land. In some parts of the South, on the other hand, the contracts are said to have grown looser and looser, until the tenants have come to ignore their landlords.⁷ The persistence of tenancy in the South, notwithstanding its serious drawbacks, is attributed to the desire of land-owners to be free of the trouble of managing their farms in person, while the negro tenant, on his part, is glad to be his own master and to be free to go and come as he pleases. This lack of supervision results in deterioration of the property, and also, it is said, has a bad moral effect upon the negro tenants.⁸ Another reason for the prevalence of tenancy in the South is found in the economic difficulty of paying cash wages, especially when the price of cotton is low; and one witness says he can not get the laborers to work for wages while his neighbors farm on the other plan.⁹ On the other hand, witnesses who make a practice of paying cash wages testify that it is the more satisfactory system, and that the farmers who adopt it are the most successful.¹⁰ The intelligent and economic cultivation prevailing in southern Louisiana is attributed to the universal custom of working hired-labor under intelligent supervision.¹¹ There is some evidence that, from the standpoint of the laborer also, a cash wage, even as low as \$6 or \$8 a month, is preferable to the system of crop sharing, under which the tenants share also the risk of the business.¹²

Crop liens in the South.—The scarcity of money in the South at the close of the civil war rendered it apparently necessary to make some provision for a credit system, and nearly all the Southern legislatures passed crop lien laws. While something of this kind may have been a real necessity at the time, it is generally agreed that the continuance of the crop lien system has been detrimental to Southern agriculture. The merchants who loan money or make advances of supplies on crop liens protect themselves by requiring the borrowers to plant a specified acreage of cotton, the principal money crop, and the system thus causes overproduction of cotton and prevents diversification. The debts secured by the crop fall due in October, and thus the greater part of the cotton is forced into the market at about the same time, depressing the price. The tenant farmers are tempted by the credit

XVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

system to buy more freely than they would if paying cash, and if they succeed in getting out of debt at the end of the crop year they become involved again almost immediately.¹ The risk of the merchant who sells on credit is so great that a high rate of profit is charged on these credit sales.²

Several witnesses express the opinion that the crop lien laws should be done away with.³ Mr. Holmes suggests that the extinguishment of the lien system might be brought about gradually by first limiting the maximum credit to a certain percentage of the value of the cotton produced, this percentage to be diminished year by year, in order to compel the planter to produce the principal portion of his supplies. It is thought that this plan would have the effect of raising the price of cotton.⁴

Interest and banking in the South.—Many witnesses complain of the scarcity of money and the high rates of interest prevailing in the South as among the Southern farmer's most serious disadvantages. Not only are the nominal interest rates higher than in the North, but in many cases money lenders exact additional payments in indirect ways; for example, a planter may borrow from a cotton factor nominally at 8 per cent, but is also obliged to agree to send the factor a certain amount of cotton and to pay him a commission of \$1.50 a bale for disposing of it, and this commission must be paid even if the planter fails to raise the prescribed amount of cotton. In some parts of the South money lenders have gradually come into possession of many of the plantations.⁵

The difficulty of borrowing money at reasonable rates of interest in the South is attributed to the prohibition of loans on real estate by national banks, and to the prohibitory tax of 10 per cent on the circulation of State banks.⁶ The establishment of numerous new banks in some parts of the South during recent years has relieved the stringency of the money market to some extent.⁷

AGRICULTURAL LABOR.

There is much evidence to the effect that the general condition of agricultural laborers has improved during the latter part of the nineteenth century. While farm work is rendered less severe than formerly by the use of improved machinery, wages have risen. Farm laborers are declared to be as well off as their employers, or, since the fall in the prices of farm products, even better off than some of the farmers who employ them.⁸ It is also said that there is a greater opportunity for laborers to rise to independent positions in agriculture than ever before.⁹ In some localities it is common for farm laborers to own their homes,¹⁰ but it is estimated that the farm laborers of Louisiana own less property per capita than at the beginning of the past decade.¹¹

Some farmers prefer to employ single men and board them in their own families so as to have them at hand, others prefer to hire married men, who are more apt to remain permanently, and to provide them with tenement houses, gardens, and perhaps a cow or horse. Mr. Greeley, of South Dakota, suggests that the solution of the hired-help problem is to be found in the encouragement of the married laborer.¹² Professor Davenport, of the University of Illinois, finds more married men employed than twenty or thirty years ago, but the opposite tendency is noted in other localities, and the youth of most farm laborers is cited as evidence that the hired men in time become independent farmers.¹³ On the other hand, Profes-

sor Davenport notes a diminution of the average farm laborer's ambition to become an independent farmer, and a tendency to work without any very definite object in view, and so without as much incentive to economy as formerly.

Duration of employment.—One of the principal disadvantages of farm labor is irregularity of employment. While some laborers are employed throughout the year, it is more common to be employed only from six to eight or ten months; and those who are hired as harvest hands of course obtain much less work.¹ On dairy farms the laborers are employed the year round,² and there is some testimony, for example from Massachusetts and New York, to the effect that a good worker can usually find work at all seasons.³ In the South there is more work that can be done in the winter than in the more severe climate of the Northern States.⁴ On the sugar plantations in Louisiana there is a time during the winter when part of the hands are not needed, but some of the laborers work the year through.⁵ The difficulty in the South, so far as regularity of employment is concerned, seems to be due to the desire of the laborer for a respite from work rather than from lack of opportunity to work.⁶ This inclination to get along without working part of the year is not confined to the South, however.⁷

The greatest irregularity of employment is said to be found where one or two staple crops are raised to the neglect of diversified agriculture. This is especially true in the grain-growing districts of the Northwest, but is also true where cotton is raised to the exclusion of other crops. Wherever diversified farming is practiced the amount of transient labor is relatively decreasing, and the duration of employment is increasing.⁸

Scarcity of farm labor.—Farmers from different parts of the country complain of the scarcity of farm labor, and especially of the difficulty of securing and of keeping reliable laborers. This difficulty is perhaps greatest in the vicinity of manufacturing establishments, which are said to take the best laborers from the country, and in sections where railroads or other public works are being constructed. The difficulty of obtaining enough labor is most acutely felt where an unusual number is required for a few weeks, as in the wheat harvest⁹ and in the raising of sugar beets.¹⁰ In other cases the complaint is of the inefficiency and irregularity of the workers, rather than of the impossibility of securing a sufficient number. One of the most frequent complaints made against the negro laborers of the South is that they go about from plantation to plantation whenever they have an opportunity of bettering their condition. A Tennessee planter speaks of the impossibility of getting white men to take charge of his dairy work.¹¹ A common custom in the South is for farmers to maintain tenant houses for the negroes, so that they can more easily be found and hired when wanted. Another plan is to keep a commissary and furnish supplies on credit.¹² In some parts of the country it is a common practice to secure farm laborers through employment bureaus. Thus the farmers of Vermont secure immigrants from the immigration offices at eastern ports,¹³ and bureaus have been organized in Western cities to send men out to the surrounding country.¹⁴ In California Chinese laborers are secured through Chinese labor bureaus or through the Six Companies.¹⁵

Hours of labor.—While one witness testifies that the hours of farm labor have increased since the introduction of improved agricultural machinery,¹⁶ the preponderance of evidence is to the effect that they have been considerably shortened

during the past 40 or 50 years. In many localities the customary duration of work is said to be about 10 hours a day; in Illinois the hours in the field are said to have been diminished to about 9 a day. The chores in the morning and evening, however, make the actual hours of work somewhat longer than stated,¹ while on dairy farms the hours are longer than elsewhere. In the Northwest and in the South the general custom seems to be to work from sunrise until sunset, sometimes, however, with as much as an hour and a half or two hours nooning;² and in some parts of West Virginia the hours of work are from daylight to dark.³ In the South Saturday is generally either a holiday or a half-holiday. Mr. Hale estimates that the hours of labor in the South are from 8½ to 9 a day in the shortest days and from 12 to 14 in the longest days of the year, averaging at least 11 hours a day of field work.⁴

Farm wages.—The general tendency of farm wages has been upward since the end of the period of inflated currency, though the recent industrial depression had its effect upon agricultural wages for a few years after 1893. In 1895 the average monthly wage, without board, was \$29 in the Eastern States, \$23.80 in the Middle States, \$12.71 in the Southern States, \$30.04 in the Mountain States, and \$31.68 in the Pacific States.⁵ Farm wages vary greatly, however, even in the same locality, according to the character of the work and the experience and skill of the laborer. Truck farmers, market gardeners, and florists pay higher wages than general farmers because they require expert labor for a short season, but long hours, and also because the proximity of cities increases the demand for labor.⁶ In the Northern States farm labor is nearly always paid in cash, usually once a month or as the money is needed, and a balance is often left in the farmers' hands until the final settlement at the end of the season.⁷ In the South wages are sometimes paid in provisions or by store orders;⁸ while instead of the Northern custom of boarding the laborer at the employer's table, stated rations are often issued in addition to a cash wage. In Maryland the custom of furnishing rations is on the decline.⁹ The difference between wages with board and without board in 1895 was \$5.67 for the country as a whole, but only \$4.03 a month for the Southern States, showing one effect of the custom of issuing uncooked rations.¹⁰

On the cotton plantations of the South it is customary for women and children to hoe and pick cotton.¹¹ Children as young as six years of age sometimes pick cotton, and boys of ten become plowmen. This child labor on farms is not confined to negro children.¹²

Cotton is sometimes cultivated on the acreage plan, the laborer being paid \$4 to \$5 an acre.¹³ In the North a system of profit sharing is sometimes adopted, under which, after the owner is paid a certain rate of interest on the value of his property and the laborer a certain rate of wages, the surplus is divided equally. In other cases the laborer is paid so much a bushel for raising corn.¹⁴ A survival of the "bee" may be found in some localities in the custom of exchanging labor, as for example in filling silos.¹⁵

The average earnings of farm laborers, after making allowance for the period of unemployment as shown by the Eleventh Census, are found to be only \$215 a year, and the census figure for unemployment is criticized as being too small. Agricultural labor is found to be the lowest paid of all the great groups of occupations, even allowing for the laborer's garden and other privileges.¹⁶ Farm laborers are

often able, however, to save something out of their wages; more, perhaps, than men employed in cities at much higher wages. A young unmarried man who takes his pay partly in board has few necessary expenses, and a married farm laborer's family can be supported in a large part from the products of the garden, poultry, and one or two cows.¹ In contrast with the low wages of the average farm laborer should be mentioned the occasional large salaries paid to plantation managers, who sometimes get as much as \$2,000 a year, or, in certain cases where scientific skill is required, even greater amounts.²

The tenant houses provided for negroes in the South seem to be in most cases furnished without charge. This is the general custom in Louisiana at least, the only condition of occupancy being that the tenants shall work on the owner's plantation whenever called upon; if one refuses to work he must vacate the house. In some parts of the South the tenants are required to work for two days a month to pay the rent.³

In some instances where a large number of laborers are required at a particular time of the year, as for fruit picking and packing, and for thinning sugar beets, a sort of camp is established either in a tent or in a more permanent structure, and meals are furnished at about cost.⁴

The packing of fruit, which requires considerable skill, is done sometimes by women and children, while in California Chinese and Japanese are sometimes employed for the purpose, and are said to be the best fruit packers available. The California fruit growers say that it would be practically impossible to harvest their crops without the Chinese.⁵

The Negro as a farmer and as a farm laborer.—From the agricultural standpoint the "negro problem" is very closely associated with the general problem of farm labor. There is much conflicting testimony as to the character of the negroes and as to their industrial value. In some cases they are said to be indolent and unreliable,⁶ but there is some testimony to the effect that they work better and even more continuously than white men.⁷

Several witnesses testify to the trustworthiness of negro laborers,⁸ and there is testimony to the effect that negroes sometimes fill places of responsibility on Southern plantations.⁹

Intemperance is considered one of the greatest curses of the colored race, but it is pointed out that the negro's propensity for whisky was acquired by imitating the white man.¹⁰ The negroes are charged with many forms of immorality,¹¹ but there has been a marked diminution of lawlessness since the years following the war,¹² and it is said that the negro laborer seldom shirks or repudiates his debts.¹³ Southern planters complain of the migratory disposition of the negroes, but this restless disposition, like the propensity for whisky, is said to have been acquired from the white man.¹⁴ The best friends of the negro admit that he is inclined to be improvident,¹⁵ and that the best results are secured when he works under supervision;¹⁶ yet many negroes have become independent farmers and have made some progress in the acquisition of property.¹⁷

Negro education.—Some Southerners are of the opinion that education is a detriment rather than an advantage to the negroes, making them discontented with

farm work and not improving their morals.¹ This belief may partly explain the discrimination against the negro schools in certain States, at least in the salaries paid the colored teachers.² Yet there is testimony to the effect that equal school facilities are provided in some of the Southern States,³ and that the Southern whites are in favor of negro education.⁴

There is an annual migration of negro agricultural laborers from Virginia and other Southern States to the North, at least as far as New Jersey, where they readily find employment during the crop season. In some cases they remain permanently in the North.⁵

It is thought by some witnesses that the labor of the negroes was more productive under the system of slavery than it is at present, and also that the laborers were better taken care of than now;⁶ but it is also said that their labor cost the slave owner more than is paid under the wage system, and there seems to be no desire to return to the system of slavery.⁷ Yet comparisons between the elder negroes who received their training under the system of slavery and the younger generation are very much to the disadvantage of the latter. It is said that the younger negroes are discontented, idle, and disinclined to receive instruction.⁸ Incompetence of the negro as a farmer is even assigned as one of the great causes of agricultural depression in the South. The specific charges brought against him in this connection are his inability to use improved machinery, his exclusive cultivation of cotton, and the necessity of white supervision. He is also said to be cruel and careless in his treatment of stock.⁹ His low standard of living is also mentioned as a cause of cheap cotton.¹⁰ On the other hand, the negro has a certain economic advantage over the white farmer in the South, in that he is his own laborer, and as a result of this the negroes of the Black Belt can afford to pay more rent for their land than white tenants can.¹¹ Several witnesses agree that, however great his delinquencies, the negro is after all the best agricultural laborer available for the South; indeed, there seems to be a quite general agreement that negroes are better adapted to farm labor in the South than white men,¹² though some Louisiana farmers prefer Italians.¹³

One proposed solution of the negro problem is the separation of the races and the colonization of the negroes, either in some part of this country or elsewhere;¹⁴ but there is considerable opposition to this plan among Southern planters, partly because of the feeling that the negro is needed in the South as a laborer.¹⁵ It is suggested, however, that the overcrowded agricultural communities of the South might be gradually thinned out by sending some of the negroes into the Northern States.¹⁶ Mr. Dillingham emphasizes the necessity of further investigation of actual conditions before the negro problem can be satisfactorily solved, but agricultural education is proposed as an important element in its solution.¹⁷

Foreigners as farmers.—While there is a feeling that the United States has been too generous in encouraging immigration, especially by its liberal public land policy,¹⁸ high tributes are paid to the general intelligence of the foreigners who have settled upon the farms of America: they are said to have elevated the character of Western and Northern agriculture, because they have appreciated the necessity of keeping up the fertility of the land and tilling the soil thoroughly.¹⁹

Immigrants from Holland have, in various localities, reclaimed lowlands which might otherwise have remained useless.¹ While the foreign-born farmers are at a disadvantage because of the time it takes them to adapt themselves to changed conditions,² their careful agriculture and their economy have enabled them in many cases to acquire considerable property, and immigrants and the children of immigrants often purchase farms from American farmers.³ Even Chinese farmers have, in many cases, become owners of fruit plantations in California.⁴ The most general complaint against the foreign farmers arises from their tendency to clannishness and to the preservation of their own languages and customs, which make them slow to become Americanized.⁵ Yet Dr. Crowell maintains that certain colonies of foreigners, such as the Pennsylvania Dutch, the Scandinavians in the Northwest, and the Huguenots of North Carolina, have, by reason of that very solidarity, preserved their agricultural instincts and abilities on a high level. Dr. Crowell considers the economic traditions of the European farmer as among the most valuable assets of American agriculture.⁶

Agricultural distribution of immigrants. (See also Vol. XV, Part III, Chapter X.)—Mr. Godwin, of South Dakota, calls attention to the desirability of distributing immigrants throughout the farming districts of the West, where he says any sober, land-loving man, with a little agricultural experience, would have no difficulty in working into permanent employment. He thinks this would be of mutual advantage to the country and to the immigrants.⁷

Public lands.—While there is some criticism of the Government's land policy, the extraordinary development of American agriculture is attributed by one witness to liberal land laws and the admission of foreign labor to occupy free lands.⁸ Most of the claims taken up in North Dakota are said to have passed from the hands of the original settlers either through voluntary sale or mortgage foreclosure.⁹ While most of the public domain has been disposed of, except in the arid and semiarid regions, there still remain considerable areas of State and railroad lands.¹⁰ Several of the Western States lease part of their public lands.¹¹

Emigration to Canada.—There has been a noticeable emigration of farmers from some of the Western States, such as Michigan and South Dakota, to north-western Canada, induced by agents of the Canadian government; but most of those who have migrated to Canada from South Dakota are said to have returned.¹²

THE RURAL EXODUS.

Abandoned farms.—The abandonment of farms in New England is said to have begun about 50 years ago. The two important causes of this rural exodus appear to be the rapid development of the West and the attractions of the cities, the former cause being assisted by cheap transportation and local discriminations in freight rates, and the latter being both cause and result of the difficulty of obtaining suitable farm laborers, especially for truck farming. A contributory cause is said to be the demoralizing effect upon agriculture exerted by summer boarders.¹³ Professor Bailey remarks that many of the farms now abandoned would never have been settled if the more fertile lands of the West had been accessible earlier, and that all the more fertile accessible lands in the East are still good farming areas. He regards the abandonment of the unfertile farms as a necessary and desirable change.¹⁴ In Maryland the abandonment of farms is attributed to the

XXIV. THE INDUSTRIAL COMMISSION:—AGRICULTURE.

loss of farms by the original owners through mortgage foreclosures, and to the exhaustion of the soil by continuous farming.¹

Several of the New England States seek to bring the abandoned farms back into use by advertising them for sale. Three-fourths of the abandoned farms in New Hampshire have been taken up, in many cases by people of wealth for summer residences; and in Massachusetts, also, there are now said to be practically no abandoned farms.²

The growth of cities.—The movement from country to city has been going on for centuries, and seems likely to continue. While the movement is sometimes attributed to the depression of agriculture, Mr. Powers finds the fundamental cause in the increased productiveness of farm labor, which makes it possible for a smaller proportion of the total population to produce food enough for all, thus giving opportunity for the development of manufactures and other industries.³

It is pointed out that the trend to the cities has been accompanied not only by a decline of agriculture in New England, but also by the decline of the smaller manufacturing industries in the hill towns, where abandoned wagon shops, shoe shops, sawmills, etc., are found, as well as abandoned farms.⁴

The difficulty experienced in getting reliable farm labor has led a great many to give up agriculture.⁵ A part of the movement to the cities is explained by the difficulty of finding room on one farm for all of the farmer's sons;⁶ and the migration of the most intelligent young men to the city is assigned as a cause of the diminished efficiency of farm labor.⁷

Aside from the underlying economic causes of the movement to the cities, much stress is laid upon the desire for an exciting environment and for the social advantages of the city. The absence of good roads and good schools in rural districts is also mentioned as contributing to the movement.⁸ Among other causes mentioned are the higher wages paid in the cities, the development of industries along mechanical lines, the success of individuals in commercial and industrial occupations and the apparent ease of their lives as compared with the hard work of a farm, the opportunities for advancement in the city, and the opportunities for the employment of the various members of the family. It is also said that many young men have an idea that farm work is degrading, and that some boys and girls are obliged to work so hard on farms that the thought of farming is distasteful to them throughout life. In parts of the South the cotton mills have drawn heavily upon agricultural labor.⁹ Attention is called to the disposition of the American to engage in commerce and speculation rather than depend upon the slow processes of agriculture. The New Englander is said to be a man of the city rather than of the country, and the children of native Americans prefer school teaching or work in a store to manual labor.¹⁰ The lack of steady employment on farms is mentioned as one of the causes of the movement to the cities, which is also attributed in part to the failure of attempts to farm on unsuitable land or by men not adapted to agriculture.¹¹

It is pointed out that there is nothing alarming in the migration to the cities so long as people are free to go and free to return, and it is predicted that the development of transportation facilities will lead to the return of men to the country as they grow older or when work is slack in the cities.¹² Already there is some evidence of a reaction from the movement to the cities, which manifests itself in a

slackening of a movement away from the farms and in a tendency to return from the city to the country.¹

Among the remedies which are suggested for the too rapid depopulation of agricultural districts are a wider education of farmers along agricultural lines,² better roads and schools, and other conveniences in rural districts.³ It is also suggested that if farming can in any way be made more profitable the tendency will be checked.⁴ One witness suggests that the tendency will cure itself through the difficulty of making both ends meet in the city, even with a fair salary.⁵ While congestion in the cities and the scarcity of farm laborers may both be relieved to some extent by finding employment on farms for men from the cities, the plan of sending men ignorant of farming into the country to farm on their own account is criticised as likely to inflict an injury both upon the men most directly concerned and upon the community at large.⁶

Relative advantages of city and country.—Nearly all the witnesses who discuss the relative advantages of city and country life consider country life the more desirable, though Mr. Hanley, while recognizing the moral dangers of the city to young men and women suddenly freed from parental restraint, also emphasizes the lonesomeness and monotonous character of farm life and work, which, he says, cause farmers' wives and daughters to break down physically and mentally.⁷ The isolation of the farm, however, is growing less with the development of trolley lines, better wagon roads, rural mail delivery, neighborhood telephones, etc., and the wide dissemination of books and papers.⁸ Mr. Powers thinks the style of living of the uneducated farmer is about the same as that of the average day laborer in the city, while he knows some successful farmers who live better than the average lawyer.⁹

The chances of economic success are said to be greater in agriculture than in other industries, for men of equal mental equipment.¹⁰ A man adapted to agriculture can be reasonably sure of at least making a living on a farm.¹¹ While a man who is able to control large interests is likely to come into that control more readily in the city than in the country, one who would remain a workingman in the city has a better opportunity to become influential in the country than in the city.¹² One witness, however, maintains that, as a general rule, an industrious and frugal young man can succeed better in the city than in the country, notwithstanding the difference in the cost of living.¹³

In discussing the rate of profit on the capital invested many witnesses agree that it is much less than in other kinds of business;¹⁴ but an investment in a farm is considered safer than mercantile investments, and the difference in the apparent rate of profit is said to be due to disregarding the products consumed on the farm and the rental value of the farmhouse; making these allowances, Mr. Greeley maintains that agriculture is more profitable than other occupations.¹⁵ Mr. Holmes calculates, on the basis of the value of agricultural products as given in the Eleventh Census, that the farmers of the United States, if allowed reasonable interest on their capital, receive no remuneration for their labor; but the general opinion is that the census figure is too low. Mr. Holmes attributes the small income of farmers, and also the small wages of farm laborers, to the small value of the wealth they produce as compared with workers in other industries, and

XXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

points out that in the Western States, where the product per capita in agriculture is greatest, the rate of farm wages is also high.¹

Dr. Crowell explains the comparatively low profit of agriculture by the theory that the farmer is governed by the law of diminishing returns, getting less than a proportional return for additional amounts of capital and labor applied to the land; and by the persistence of the competitive principle in the sale of agricultural products, while in manufacture, after a certain limit of competition is reached, there is a tendency to combine for the purpose of controlling production and prices.²

AGRICULTURAL EDUCATION AND RESEARCH.

Agricultural colleges.—The development of agricultural colleges and experiment stations in America is part of a world-wide movement for the organization of technical education and scientific research in agriculture, due mainly to Governmental action, though there is at least one case in England in which a large private fortune has been devoted to experimental work in agriculture.³ The American agricultural colleges are organized under the land-grant act of 1862, which granted to each State and Territory 30,000 acres of land for each Representative and Senator in Congress; though a few States had even before that date made some efforts in the direction of establishing such colleges.⁴

There is some dissatisfaction with the manner in which the land-grant funds have been disposed of. In many cases the funds were turned over to colleges and institutions the management of which took little interest in agricultural education.⁵ At the time of the land grant there was comparatively little demand for scientific instruction in agriculture, especially in the West, because large crops could be raised without special agricultural knowledge or intensive culture; but with the necessity of producing the best possible results on each acre of land there is arising a demand for scientific methods, and hence for better education.⁶ Moreover, the principles underlying agriculture had to be discovered before they could be taught, and it has taken time to develop a literature upon which agricultural education may be based. While the universities were longer in working out a satisfactory basis for agricultural instruction than the separate colleges, which had but one problem to solve, a number of the State universities have recently established very strong departments of agriculture.

Instruction in the mechanical arts was naturally developed more rapidly than agricultural instruction, because of the relative simplicity of mechanical problems and the rapid development of mechanical industries.⁷

There is some complaint relative to the large amount of attention still given to the mechanical arts in some of the agricultural colleges, and it is suggested that the curriculum should be modified so as to lay more stress on agriculture.⁸ It is also suggested that if the agricultural and mechanical colleges were kept distinct from the State universities they would be more likely to develop an enthusiasm for agriculture.⁹ Other witnesses, however, point out certain advantages of union, and predict that in the future the best work in agricultural education and research will be done at the universities.¹⁰ The Association of Agricultural Colleges and Experiment Stations is studying the methods of teaching agriculture with a view to further improvement.¹¹

There is a demand for agricultural schools below the college grade, at which

boys could obtain practical agricultural training.¹ The University of Minnesota has met this demand by the establishment of a School of Agriculture of high-school grade, nearly all the graduates of which return to farm homes; and a similar school has been started at the University of Nebraska.² The practical agricultural training at such institutions as Hampton and Tuskegee is universally commended.³

At some of the agricultural colleges students are enabled to pay their way, in whole or in part, by working on the college farm at so much an hour, and so gain practical agricultural experience.⁴ Many of the colleges have established winter courses along practical lines for farmers who are unable to take a complete college course, and in some cases special schools have been established to prepare students for such special industries as dairying, sugar-cane growing, or forestry.⁵

Critics of the agricultural colleges point to the large number of their graduates in other than agricultural occupations in support of their assertions that the curricula are not sufficiently devoted to practical agriculture. A census of the graduates of the Michigan Agricultural College taken some years ago showed that a little more than half of the graduates were engaged in agriculture, and the proportion of the graduates of other professional schools who follow through life the calling they were educated for was found to be less than 50 per cent. In explanation of the tendency to go into other employments, it is pointed out that it requires capital to acquire a farm, and that it is therefore more difficult for a young man to establish himself in agriculture than in a profession; so there has been a tendency for agricultural-college graduates to teach school for a time, or do something else by which they could get more money than by doing ordinary farm labor. Nearly all the recent graduates of the Michigan Agricultural College look forward to owning land as soon as they are able. It is also pointed out that many young men attend the agricultural college without any idea of practicing agriculture, because it is a cheap place to get an education; yet some of these afterwards do become farmers.⁶ Among the graduates of agricultural colleges, besides those engaged in practical agriculture, are a number of directors of experiment stations, professors of agriculture, and officers of agricultural colleges.⁷ Students who take special courses in dairying or sugar making are apparently quite apt to follow the occupation for which they are trained. The agricultural college of the University of Wisconsin has found places on farms for large numbers of its graduates.⁸ Agricultural-college graduates who engage in practical agriculture are said to be more successful farmers than farmers of less education, other things being equal,⁹ and are thought to exercise a very beneficial effect upon the agriculture of the localities in which they settle, becoming centers of better agricultural methods.¹⁰

Experiment stations.—Experimental work in agriculture has grown up as a natural result of the establishment of agricultural colleges. There were 17 experiment stations in the country before the passage of the Hatch Act (1887) making an annual appropriation to each State and Territory for the maintenance of such stations. The work of the stations is classified under four heads: (a) Police duties connected with the control of fertilizers, dairy products, etc.; (b) study of the natural resources of the States; (c) demonstration experiments applying scientific discoveries to local conditions; (d) investigations for the discovery of new truths and new applications of old principles.¹¹

XXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

The experiment stations, like the agricultural colleges, are subjected to some criticism on the part of those who think that their work should be made of more practical value to the average farmer who is unable to employ expensive methods;¹ but the attitude of farmers toward the experiment stations is increasingly friendly throughout the country, and it is not questioned that their work has been of great advantage to agriculture, not only in inducing improved methods, but also in showing the possibilities of agriculture in the various localities and encouraging diversified farming, both in the North and in the South. It is suggested that they should do more work of this latter kind.²

The movement for agricultural education and research in the United States has resulted in a body of trained experts and up-to-date literature on American agriculture; wide distribution of a large amount of useful information, and a breaking down of the idea that agriculture is nonprogressive, while the competition of improved methods has rendered the condition of ignorant, nonprogressive farmers worse than formerly.³ The attitude of the farmer toward the scientists has changed in recent years. Experts who were formerly listened to with indifference, because of the farmer's contempt for theory, have proved their right to be considered authorities in practical agriculture, and are listened to with the greatest interest;⁴ and while practical farmers were formerly the most popular speakers at farmers' institutes, there is a growing demand for scientific lecturers.⁵

Common schools in rural districts.—Among the causes most often assigned for the depopulation of the rural districts are the inferior school facilities to be found there, and the neglect of subjects connected with agriculture in the common-school curricula. In Pennsylvania the rural school districts receive from the State only about half as much for each pupil as is paid to Philadelphia.⁶ In some parts of the South the school facilities are said to be poorer than thirty or forty years ago, notwithstanding some improvement in recent years, and the funds insufficient to keep the schools open more than a few months in the year.⁷

The ordinary common-school curriculum is criticised as being very poorly adapted to the needs of those who are to engage in farming. Such pupils learn nothing of the profession they are to follow. School children go into an artificial world having no relation to rural life, and read about phenomenally successful men in other than agricultural lines, but nothing about crops, plant and animal foods, or even the nature of the soil.⁸ The lack of prosperity in Southern agriculture is attributed to this educational deficiency,⁹ and it is said that the public schools as at present conducted unfit the negroes, especially, for the struggle for existence, tending to make them think they can live without working.¹⁰ Manual training of every kind is neglected.¹¹

The teaching of elementary agriculture in the common schools in agricultural districts is earnestly advocated, and nature studies are recommended for both city and country schools.¹² Several of the States have already taken up the matter of nature study, New York, Pennsylvania, and Massachusetts taking the lead in this direction.¹³ The establishment of township graded and high schools in country districts is advocated as another means of improving the educational facilities of the country.¹⁴

EXHAUSTION AND IMPROVEMENT OF SOILS.

Until recently American agriculture has consisted in raising cheap crops, without much reference to the effect upon the soil; but it is argued that a man who leaves a farm poorer than he found it has committed an offense against society.¹ While the exhaustion of soils may be excused on the ground that the future is necessarily forgotten because of present necessities,² it is pointed out that it is possible to get as much income while improving the soil as by letting it deteriorate.³

In the South one cause of diminished fertility is the system of cultivation which leaves the land bare a large part of the year, so that the soil is decomposed by the continued warmth and humidity, thus eliminating the organic elements.⁴ Notwithstanding the desolate appearance of much of the land of the East and South, however, it is denied that it lacks the needed elements of plant food. Mr. Whitney, Chief of the Bureau of Soils in the Department of Agriculture, says he has never seen a case in which the exhaustion of soil was probably due to the absence of plant food and that all the soils of New England and of the South have the essential elements for crop production, which need only to be rendered available by methods which will facilitate the natural weathering of the soil. With proper cultivation it is possible to obtain fair crops from the same land for an indefinite period. The soil of the South has never been thoroughly tilled, and deep plowing brings out an abundance of plant food.⁵ The reputed exhaustion of soils in Maryland and Virginia, and in the South generally, is attributed to injudicious methods of cultivation and to social conditions unfavorable to agriculture, rather than to the actual exhaustion of plant food. Mr. Whitney contrasts the typical Maryland farm, managed by an overseer or a tenant farmer, and producing such staple crops as grain and tobacco, with the typical farm of Lancaster County, Pa., where the farm work is done by the owner and his family, and where there is such a variety of products that very little is either sent out or brought into the county. Mr. Whitney admits, however, that the cultivation of cotton has resulted in a great loss of organic matter, leaving much of the Southern soil poor in the organic substances necessary for the weathering of the soil.⁶

Maintenance of fertility.—In some parts of the country the fertility of the soil has been actually increased. Thus the soil of Illinois, where it has been properly managed, is said to be more fertile than when the prairie was first broken. The increase of fertility is attributed to rotation of crops, cultivation of clover, careful tilling, and use of manure.⁷ In Virginia, also, the yield per acre is said to be larger than in the past where the soil has been properly cultivated,⁸ and in Alabama, lands which formerly produced less than one-fifth of a bale of cotton to the acre have, by the use of fertilizers, been made to produce a bale to the acre.⁹ In New Jersey the land is said to be improving where enough stock is kept.¹⁰

The crops grown the first year on prairie soils are said to be small as compared with the second year, and small the second year as compared with the third, but fair beginning with the third year.¹¹

The principal methods used for maintaining fertility of the soil are rotation of crops, especially the use of leguminous crops to gather nitrogen from the air, thorough tillage, and artificial fertilization. Attention is called to the importance of the bacteria which grow in the tubercles on the roots of leguminous plants. Some of the leguminous crops will not grow unless these bacteria are in the soil,

⁹ Poole, 924.

¹⁰ Coles, 123.

¹¹ Moran, 708.

and cultures of these bacteria are sold in Germany, and to some extent in this country, by the use of which the yield may be greatly increased.¹

While nitrogen can be supplied to the soil through leguminous plants, lost potash and phosphoric acid must be returned by artificial fertilization.² Fertilizers are sometimes used to neutralize the acidity of the soil, which is more common than was formerly supposed, or to balance the ratio of the soil constituents in some other way.³

The main sources of supply for the animal substances used as constituents in commercial fertilizers are Chicago, Omaha, and Kansas City, while the rock phosphate comes from South Carolina, Tennessee, and Florida, and potash from Germany. The phosphate industry of South Carolina has declined somewhat in recent years because of the discovery of the Tennessee and Florida phosphates.⁴ Tankage from slaughterhouses is used largely in sugar-cane culture in Louisiana, and cottonseed meal is used as a fertilizer both there and elsewhere in the South.⁵

Mr. Dye expresses the opinion that the sewage of cities would be of great value if utilized as a fertilizer.⁶

Prices of fertilizers.—Phosphates have been growing somewhat cheaper because of the large territory from which mineral phosphates are derived,⁷ but there was a sudden advance of from 15 to 25 per cent in the prices of fertilizers early in the year 1900, which is attributed to the influence of a trust, the raw material being said to be controlled wholly or in part by the companies making the fertilizers.⁸

Fertilizer laws.—The Massachusetts Experiment Station is credited with having first shown that farmers were being cheated by dealers in commercial fertilizers, and with having secured the passage of the Massachusetts fertilizer law, which has been followed with variations by many other States.⁹ Laws governing the inspection and sale of fertilizers now exist in most of the Eastern States, and the desirability of a more uniform system of laws, including national regulation of interstate trade, is suggested.¹⁰

Intensive and extensive culture.—Two witnesses express the opinion that much harm has been done by the excessive and constant use of commercial fertilizers, without the intensive methods which should be employed with them.¹¹ On the other hand, it is claimed that American farmers have adopted intensive methods as fast as the conditions have justified.¹² A farmer can not afford to spend very much money in maintaining the fertility of cheap lands, but when the yield diminishes and the scarcity of lands increases their value, more intensive methods will doubtless be introduced.¹³ Even now, intensive farming is claiming the attention of the people in some parts of the country, at least, more than ever before.¹⁴ One of the most striking examples of intensive culture is the raising of tobacco and of pineapples and truck crops under cheese-cloth covers. While this involves an initial expense of \$500 an acre in the tobacco fields of the Connecticut Valley, it is said to yield in large profits.¹⁵

Size of farms.—Nearly every witness who discusses the subject is of the opinion that small farms are of more advantage than large ones, partly because they make more thorough cultivation feasible, and partly because comparatively few men can direct the labor of others to advantage.¹⁶ Some witnesses emphasize the social advantages of the system of small farms, which brings the farmhouses nearer

together and near to the schools.¹ One witness thinks the percentage of profit is larger on bonanza farms than on small farms;² but the preponderance of testimony is to the effect that the bonanza farms are in many cases both unprofitable to their owners and detrimental to the communities in which they are situated. It is charged that bonanza farmers fail to take advantage of the rotation of crops, and exhaust the soil.³ It is believed that the subdivision of bonanza farms into small tracts would be beneficial by giving employment to more people and increasing the permanent population of the locality.⁴ The chief advantages of the bonanza farms are said to lie in the marketing and shipping of the product.⁵

Drainage of swamps.—It is estimated that there are 168,000 acres of tide marshes along the Atlantic and Gulf coasts, and several million acres along the Pacific coast, which might be reclaimed for agricultural purposes, while at the same time increasing the healthfulness of the localities in which they are situated. Swamp lands which have been drained in Illinois and Michigan have become very productive and valuable.⁶

IRRIGATION.

While there are remains of prehistoric irrigation works in Arizona and New Mexico, and the early Spanish settlers in the Southwest also promptly resorted to artificial means for supplementing the scanty rainfall, irrigation by English-speaking people in the United States began only about half a century ago among the Mormons in Utah, and it was twenty years more before it was generally resorted to in Colorado, California, and other States. It is estimated that 40 per cent of the area of the United States (exclusive of the detached possessions), including most of the country west of the one-hundredth meridian, requires irrigation for successful agriculture. In the arid part of the country irrigation is not only necessary to the development of agriculture, but also, by providing a food supply, makes the development of other industries possible, and adds greatly to the attractiveness of the country. In 1890 only 3,600,000 acres of land in the arid States were irrigated. It is estimated that by the construction of reservoirs, about 74,000,000 acres, or not more than 10 per cent of the lands of the arid region, can be profitably irrigated. It is said to be no longer possible to irrigate wheat, but the possibilities of irrigation are very great for such crops as fruits and alfalfa.

Water rights.—Much litigation over water rights in the Western States has resulted from the lack of adequate laws governing such rights, and also, in Mr. Mead's opinion, from errors in the adjudication of water rights. Certain principles, however, have been established by State legislation and judicial interpretation. Thus it is settled (1) that the first appropriator from the stream has the first right to its water, the rights of subsequent appropriators following in order, and (2) that all rights must be based on the actual beneficial use of the water; but there are wide differences in the laws governing the limitations of an appropriation. In States where the irrigating canals are small and are owned by the owners of the land irrigated, the water rights are attached to the land and the appropriation limited to the needs of the land; but in some States and Territories where corporations have built extensive irrigation works, water has come to be regarded as personal property which can be disposed of like any other commodity. Especially difficult complications arise where a stream crosses the borders of a State, since in that case it can not be wholly controlled by any one State legislature. Mr. Mead emphasizes the necessity of laws for the more adequate regulation and control of water rights.

Seepage and alkali.—The loss of irrigation water by percolation where canals

¹ Wilson, 249; Budge, 850, 851.

² From, 701, 702.

³ Brigham, 17, 18; M. F. Greeley, 634; Powers, 128.

⁴ Dye, 94, 95.

⁵ Hanley, 379.

⁶ Whitnev, 884, 885.

and ditches pass through porous soil or gravel is not only a serious problem to the canal owners themselves, but is frequently the cause of injury to the lands of others. Where the seepage is not excessive it may be beneficial to the lands reached by the water, but excess of water may itself be injurious to the crops and result in an accumulation of alkali which is still more harmful. Evaporation from water surfaces, which ranges from three to six inches a month in the west, also in some cases concentrates the alkali in the water used for irrigation to such an extent as to make it injurious to crops.

In order to prevent the loss of water by seepage irrigating canals are sometimes lined or cemented. In other cases clay is dumped into the canal and distributed by agitation of the water. In California it is common to protect canals against percolation by wooden troughs or pipes.

Mr. Whitney is convinced that by using greater care in the application of water twice as much land could be irrigated with the amount of water now commonly used, and that greater care will be necessary to protect the soil from the injurious effects of overirrigation and the accumulation of seepage water and alkali.

Silt.—Another physical difficulty in irrigation is the accumulation of silt on the sides and bottom of the canals, which makes it necessary in some cases to clean out the sediment from time to time.

Cost of irrigation.—The cost of irrigation from many of the original ditches was as low as from \$3 to \$5 per acre, but as it became necessary to construct larger ditches the expense increased. At the time of the Eleventh Census the average cost of placing land under irrigation was \$12.12 an acre, and the average annual cost \$1.07 an acre. In some canals the estimates for water now run as high as \$20 an acre, which is more than can be paid in many cases, because an improved farm could be bought in the Mississippi Valley for what it would cost to develop a farm farther west by irrigation.

Public and private irrigation.—Irrigation in the United States differs from that of most other irrigating countries in that all the canals and reservoirs have been constructed by private enterprise, except that Colorado has built a few reservoirs and begun one canal with State funds. Under the system of private construction the leading consideration has been the cheapness with which water could be secured, and little attention has been paid to the development of a comprehensive system of irrigation for the future. It is predicted that along many of the streams the irrigated area can now be extended only by the construction of reservoirs. Mr. Mead distinguishes between reservoirs located on the channels of streams and those at a distance from the streams. He believes that those located away from the streams can be safely left to private enterprise, but that those built to supplement the natural flow of the streams and to meet the needs of a number of ditches or canals should be either State or national works. He points out that the arid States lack the resources for constructing canals and reservoirs, because they are sparsely populated and the public land within their borders contributes nothing in taxes and can not be used as a basis of credit in borrowing money.¹

Rice irrigation.—Irrigation is coming to be of considerable importance in the East and South as well as in the far West, especially in the production of rice. The rice lands of South Carolina were formerly protected by substantial levees built before the civil war through cooperation between individuals and the State, but these levees were destroyed during the war, and large areas of rice lands were abandoned. While the remaining rice lands of South Carolina are still flooded by the rivers without artificial means, rice is now grown in Louisiana exclusively by artificial flooding; and the success of rice irrigation in Louisiana has led to increased interest in the industry on the Atlantic seaboard.²

¹ Mead, 1049-1074; Whitney, 860-865.

² Whitney, 864, 865; Stubbs, 772, 773; Mead, 1060, 1070.

FORESTRY.

The destruction of forests is thought by some authorities to result in a reduction of the rainfall.¹ However that may be, it is generally agreed that deforestation results in irregularity in the flow of water in the streams, low water alternating with floods; for while the forest stands the snow melts slowly and the water oozes gradually through the mosses and loam to the rivers, but when the forest is destroyed the water runs much more rapidly into the streams. It is therefore suggested that preservation of forests at the headwaters of the Mississippi would save an expenditure of large sums for dikes to protect the Lower Mississippi Valley from flooding. The financial possibilities of Government forestry are illustrated by the statement that the German Government receives annually about \$95,000,000 from its forests, of which about \$55,000,000 is clear profit; while in many districts the forests supply all the revenues for schools and roads, and no taxes are levied.²

Several States have made a beginning in the direction of forestry administration. In Pennsylvania, for example, authority has been granted to purchase lands on the headwaters of rivers for forest reserves. There is also less tendency than in former times to waste timber. Whereas hemlock trees were formerly cut simply for the bark and the logs left on the ground, the wood is now utilized either for lumber or for making paper.³

New York College of Forestry.—Professor Fernow, of the College of Forestry of Cornell University, gives some account of the work of his college. The college was established by the State of New York, primarily to make an experimental demonstration of forest management with special reference to a permanent policy for the treatment of the State reservation in the Adirondacks. Forestry, according to Mr. Fernow, is the business and art of managing woodland so as to derive a continuous revenue from successive crops of merchantable timber. It is admitted that crops which take from 50 to 100 years or more to mature are not suitable for cultivation by the small capitalist. They can be grown to advantage only on a large scale, and cultivation of them is an enterprise particularly suited to the circumstances of permanent bodies like States and communities.

The State bought 30,000 acres of Adirondack woods and made over the tract to Cornell University for 30 years. A working capital of \$30,000 was provided by the State to start with, but all the further expenses of managing the tract and planting and protecting a new crop of timber on it must be met from the profits of harvesting the old crop. Over a million seedlings of conifers are already growing in nurseries upon the tract, to be set out in the forest when they attain a sufficient size.

The college course covers four years, of which only the last two, however, are occupied with special courses in forestry management. Each spring the students have a period of practical work in the forest under the direction of the instructors. The number of students is increasing, and many students from other departments of the university are taking special courses in the college.⁴

STAPLE AND DIVERSIFIED PRODUCTS.

Diversification and specialization.—It is pointed out that while there is often an overproduction of such staple articles as cotton and wheat, there is seldom an overproduction of other crops, especially of those which are used as luxuries.⁵ Many witnesses therefore recommend diversification of crops as an important means of improving the condition of the farmers, especially in the South; and there is evidence that some progress has been made in the direction of diversified

⁵ Bailey, 1011, 1012; Hale, 398.

agriculture in many parts of the country. There are, however, great difficulties in the way of introducing diversified agriculture in the Southern States. Cotton being the universal money crop, it is the only crop on which money can be borrowed, and it is also said that it is the only crop which is always certain of a market.¹ The conditions are such that it is easy for a Southern farmer to grow cotton, but if he attempts to raise other crops he must try expensive experiments, and must have capital. For those who have gone in debt in order to buy homes, it seems impracticable to discontinue the growing of cotton.² Moreover, there are cases in which Southern farmers who have tried to raise vegetables, tobacco, or watermelons have lost considerable money in the attempt.³ On the other hand, the profits on diversified crops are sometimes ten times as great as on cotton, although the precarious rainfall makes the amount of profit somewhat uncertain. The railroads gain from diversification as well as the farmers themselves, because fruits, for example, afford fifteen times as much tonnage to the acre as cotton, at a higher rate.⁴ Even where it is impracticable to raise other crops than cotton on a large scale for the market, Southern farmers often find it advantageous to produce their own supplies, and so become to a greater or less extent independent of the country stores and of the credit system.⁵ This is a return to something like the system of agriculture which prevailed before the war, when the work animals and nearly all the supplies were produced on the plantation.⁶ As regards diversification with a view to marketing the various crops, it is pointed out that the chances for diversity increase with nearness to city markets.⁷

While it is universally conceded that too much attention has been paid to a few staple crops, it is questioned whether farming is after all an exception to the tendency of business in general toward specialization. It seems possible, however, to reconcile the principle of specialization with that of diversified crops by combining specialization on individual farms with diversification in a given locality as a whole. It is not essential to diversification in this sense that every farmer should produce a great variety of crops; but each farmer may devote himself to the cultivation of the particular crops his land and capabilities are best adapted to. Thus a man who has good wheat land might supply wheat for all his neighbors, and one who has good rice land might furnish rice for an entire neighborhood. It would not be desirable for a farmer to raise wheat and rice for his own consumption alone, because they require milling.⁸

Wheat.—Attention is called to an inclination in the West and Northwest to get land into producing wheat as rapidly as possible, because cultivated land is more easily disposed of than land not under cultivation. While some increase of wheat production has been necessary to keep up with the demand, the production has at times been in excess of the demand,⁹ especially when European harvests have been good for a number of years, and the demand for wheat for export has therefore been less than usual.¹⁰ Referring to the recent discussions as to the wheat-producing capacity of the country, Mr. Powers declares that the amount of wheat that would be produced in this country, if the Liverpool price were maintained at a dollar a bushel, could hardly be calculated.¹¹

Barley.—The decline of the barley-growing business in the East, especially in New York, is attributed chiefly to the adulteration of malt by the use of substitutes for barley. It is also claimed that large malt houses have been closed by a

¹¹ Page 181.

trust which has bought Western and Canadian barley in preference to that grown in the East.¹

Yield of cereals per acre in the South.—Generally speaking, the yield of cereals per acre is much less in the South than in the Northwest. The normal yield of grain is said to be about one-third as great in the South as in the North. The frosty nights which occur in the Northern States at about the time the plant has attained its full growth favor the production of grain because of the botanical principle that the plant tends to form seed as soon as there is danger of destruction; while in the South there is a longer persistence of vegetable growth and less tendency to produce grain. Yet a phenomenal yield of grain has been produced in South Carolina by checking the vegetative growth by certain methods of cultivation.²

Profit and loss in wheat growing.—There is some testimony to the effect that grain is raised at a loss in the Northwest,³ but this is controverted by other evidence to the effect that when a farm is properly cultivated wheat raising is profitable.⁴ Mr. Greeley, of South Dakota, takes an intermediate position, maintaining that wheat does not pay year after year unless it is raised in connection with stock farming. Mr. Greeley knows of farmers who have turned to stock raising and yet raise more grain than before. The attention of the whole Northwest, he says, is turning to stock.⁵

Mr. Coles, of New Jersey, does not regard wheat as a paying crop in that section, but adds that it is sometimes necessary to grow it for the straw.

Prices of wheat.—It is stated on the authority of the Royal Commission on Agriculture that from 1849 to 1872 the production of wheat increased 70 per cent and the price 30 per cent, while from 1872 to 1894 the production increased 40 per cent and the price decreased 60 per cent.⁶ In contrast with this marked downward tendency in the English market, it is pointed out that the gold value of wheat at the farm in this country stands as high in recent years as for the years following the civil war.⁷

Cost of transportation.—It is estimated that the cost of carrying wheat from the wheat fields of the Northwest to the Atlantic seaboard is one-half as great as the original cost of production.⁸

Cost of producing cotton.—The cost of raising cotton is said to vary all the way from 3½ to 20 cents a pound.⁹ There is considerable testimony, however, to the effect that when the price of cotton is as low as 5 cents a pound it can not be raised profitably.¹⁰ Mr. Lovejoy states that cotton can not pay expenses when the price is less than 5½ cents, and that there is very little profit when the price falls below 7 cents.¹¹ One or two witnesses indicate that the cost of production depends very much upon the yield per acre. Thus it is said that when a bale of cotton is produced for every 3 acres the cost is about 8½ cents a pound, including expenses of delivery and interest and taxes; when one bale is raised on 2 acres the cost is said to be about 7½ cents, and when one bale is raised to the acre, about 6½ cents.¹²

Cotton manufactures.—Several witnesses express the opinion that the development of cotton manufactures in the south can not but be of material benefit to the section, perhaps by increasing the price of cotton, or at any rate by adding to the prosperity of the South as a whole.¹³ Dr. Crowell points out that agriculture has already improved to some extent in the vicinity of the manufacturing villages, and maintains that the agriculture of the future in the South must be built up on the basis of the market furnished by domestic manufactures.¹⁴ As an illustration of

¹⁴ Page 335.

the advantage of the nearness of cotton factories, it is stated that when cotton is low the price is nearly always higher in North Carolina than in New York.¹ Mr. Graham, of North Carolina, says he has sometimes made half a cent a pound by telephoning to the mills for the price.

In Louisiana the newer cotton factories are organized by joint stock companies—a plan which has been quite successful also in North Carolina. The shares are paid for in installments of \$1 a share weekly, each person subscribing for 10 shares at \$100 each.²

Besides increasing the profits of cotton growing, the presence of local factories, by diverting labor from the fields to the factory villages, creates an increased demand for butter, eggs, and other agricultural products.

The Southern cotton mills have the advantage of their Northern competitors in nearness to the raw material and in longer working hours; but, on the other hand, the Southern operatives have not yet become sufficiently skilled to make fine fabrics, though they are said to be making rapid progress.³

Stock raising.—The diversification of agriculture, especially by stock raising, is recommended, and it is pointed out that while stock raising may sometimes bring in somewhat less income than the growing of wheat, the profit is not so apt to be interrupted by unfavorable seasons, and the effect upon the soil is much better.⁴

Mr. Youmans, of South Carolina, testifies that he can buy Western horses more cheaply than he can raise them.⁵ In other parts of the South, also, the impression prevails that it is more economical to buy mules than to raise them, but this is denied by witnesses from Mississippi, Tennessee, and Arkansas.⁶

Truck farming.—Southern competition has been felt severely by the New Jersey truck farmers, especially when the Southern vegetables have been delayed by cold weather so that they are thrown on the market at about the same time with the New Jersey products.⁷ The Maryland truck farmers have also suffered severely from Southern competition.⁸

Dairying in New Jersey.—New Jersey truck farmers are said to be giving up that industry and going into dairying, but even in that business there is said to be no profit in supplying the New York market. In the vicinity of Elizabeth the New York trade has been discontinued. Milk which retailed in New York City for from 5 to 8 cents a quart brought the producer only 2 cents a quart.⁹

Fruit growing.—Attention is called to the advantages of fruit growing both from the standpoint of present profit and of the utilization of soils which are not well adapted to other crops. Thus, in Maryland, soils which are of no value for general farm purposes are found to be particularly well adapted to the production of late peaches.¹⁰ During the high prices of fruits which prevailed a few years ago it was not unusual for California orange growers to net \$500 an acre.¹¹ Fruit growers in West Virginia are said to have made more than twice as much money as farmers engaged in general agriculture, and a good profit is reported also from Georgia fruit farms.¹² It is suggested that the consumption of such fruits as peaches could be greatly increased by an improved system of distribution which would supply the smaller towns of the country as well as the large cities.¹³

Tobacco.—The Department of Agriculture has investigated the possibility of raising Sumatra tobacco in this country instead of importing large quantities from Sumatra. Sumatra seed has been planted in the Connecticut Valley under cheese-cloth sheds, and by a combination of the methods used in Sumatra, Florida, and

¹³ Hale, 396.

Cuba, a leaf has been produced which is pronounced by experts to be fully equal to the imported Sumatra leaf. It is confidently expected that this industry will successfully compete with Sumatra tobacco.¹

Tea.—Attempts to produce tea in this country date back to the period before the civil war, but these early attempts were discontinued. Mr. Shepard, of Pinehurst, S. C., has more recently experimented with many different kinds of seed, and has succeeded in producing tea at the rate of 400 pounds to the acre, of a quality pronounced by experts to be inferior to nothing brought to this country. On one field he has produced several times as much tea to the bush as is produced in China and Japan. Mr. Shepard is confident of the possibility of building up a profitable tea industry. Congress has made an appropriation to aid in the prosecution of his experiments.²

THE SUGAR INDUSTRIES.

The cultivation of sugar beets is becoming one of the most important of the newer agricultural industries of this country. Among the advantages claimed for sugar-beet cultivation are the following:

(1) If the leaves, crown, pulp, and molasses are returned to the soil, directly or indirectly, no loss of plant food results from the removal of the sugar itself, which contains no elements of fertility. It is considered important, however, that beets be grown not oftener than once in three or four years on the same land, and they are found to be useful in preparing the soil for other crops.

(2) Sugar beets require far more intensive methods of cultivation than most other crops. It is thought that this will tend to improve agricultural methods and teach the American farmer the desirability of fertilizing the soil.

(3) The pulp remaining after the extraction of the sugar is an excellent food for cattle and other farm animals, increasing the yield of milk in milch cows, and being favorable also to the production of a choice quality of beef. It results from this circumstance that dairy industries are sometimes built up around beet-sugar factories. The residual molasses, another by-product of sugar manufacture, is also useful as a food for cattle, being sometimes mixed with dried pulp for that purpose.³

(4) The establishment of sugar factories exerts a marked influence on the labor market, giving employment to many who would otherwise be idle, and relieving to some extent the congestion of population in the cities. The hoeing, thinning, and harvesting of the beets gives employment at light work to men, women, and children, and the hoeing and thinning are done mainly in June and July, after the close of the schools. In Europe the field hand in the sugar-beet industry usually becomes an operative in the sugar factory during the manufacturing season, and so has employment nearly the year round; and a similar arrangement has been attempted in at least one case in this country, the men employed in the factory in the late fall and winter being given employment in the fields during the summer months. It is estimated that a beet-sugar factory should support a laboring population approximately to the number of tons of its daily capacity, and that it would require 400 or 500 factories of 500 tons each to supply the American demand.⁴

(5) Owing to the custom of the sugar factories of contracting for beets before they are planted, the farmers have no difficulty or uncertainty about the disposal of their crops.⁵

XXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

(6) Wherever the beet-sugar industry has been established in this country the value of farm land has increased because of the profitability of the beet crop.¹

Profits of sugar-beet culture.—Under favorable conditions the profits of sugar-beet cultivation are large. Figures relating to the experience of 10 farmers in Michigan show that their profits, in a favorable season, ranged from \$18.85 to \$57.08 an acre. This was in an agricultural community composed largely of Germans and Hollanders, many of whom were accustomed to raising beets in their native homes.² It is suggested that foreigners have an advantage over Americans in the raising of sugar beets, in that they are not so averse to getting down on their knees, as is necessary in the thinning of the beets;³ yet it is said that American farmers in Illinois have grown better beets than could be grown by the Germans, who have the reputation of being the most skillful sugar-beet growers in the world.⁴

It is said to be profitable to raise even one or two acres of sugar beets.⁵

Sugar bounties.—The beet-sugar industry has been encouraged by several States by bounties on sugar manufactured from beets grown within the State. In some cases the payment of the bounty is conditioned upon the payment of at least a prescribed price for the beets, and in any case the theory is the bounty will indirectly benefit the farmer. In some cases, as in Michigan and Nebraska, the bounty has been discontinued after a few factories were started through the refusal of the legislature to make further appropriations for that purpose. All the witnesses who discuss the subject agree that while a bounty may be necessary at the very beginning, a permanent bounty is unnecessary. The exemption of beet-sugar investments from taxation for a series of years, as practiced in Iowa, is recommended as a desirable means of encouraging the industry.⁶

Climates suitable for sugar beets.—It is said that the farther north sugar beets can be brought to maturity the greater will be the sugar content of the beets, partly because of the longer days in northern latitudes. Excellent beets are grown in Canada, but the time for harvesting is so limited on account of the early winter that the industry has not proved as profitable there as farther south, where the beets are not quite so good.⁷ While attempts have been made to grow sugar beets in many parts of the South, it has been found that the beets grow too large and have a small sugar content.⁸ It costs no more to raise beets containing 18 per cent of sugar than those containing 10 per cent, except that a little more fertilizer may have to be used; and it pays the farmer and the manufacturer to get the largest percentage possible, because every additional per cent of sugar means a clear yield of 20 pounds more sugar to the ton, and the factories pay for the beets according to the amount of sugar they contain.⁹

Irrigation for sugar beets.—The arid region, where irrigation is possible, is pronounced the ideal place for sugar beet culture, because of the sunny days and the absolute control of the water supply. In the humid regions September rains followed by warm weather result in a second growth which injures the quality of the beet, and the muddy roads interfere with the marketing. It is predicted that sugar beets will be the most profitable crop that can be grown on irrigated lands, and that they will pay fixed charges on land worth \$300 an acre, on which grain could not be profitably grown.¹⁰

Transportation to factories.—In Michigan over 50 per cent of the sugar beets are hauled to the factories on cars from points within a radius of 40 miles from the factory. Beets are hauled to Binghamton, N. Y., from points as far away as 75 to 100 miles. Some of the Michigan factories pay the freight on the beets; in

⁹ Wiley, 664.

¹⁰ Wiley, 646, 647.

other cases they are unloaded free of cost.¹ The factory at Lehi, Utah, has inaugurated an interesting experiment by establishing substations, about 80 miles from the main factory, at which the juice is extracted from the beets and piped to the manufactory. This plan extends the area from which it is practicable to obtain beets, and makes it possible to locate the main factory at the most favorable point for getting fuel, water, etc.²

Manufacture of beet sugar.—There were 80 beet-sugar factories in operation in the United States in 1889, with a total maximum capacity of 19,000 tons daily. In May, 1900, 6 new factories were building, and still others were projected. The average size of the American factories is larger than of those in Europe, the largest being a California factory with a capacity of 3,000 tons of beets daily.³ It is thought that sugar can be made at the minimum cost by a factory with a capacity of 500 tons daily.⁴

It is claimed that the United States now has the best beet sugar factories in the world, and experts come from Europe to study them. While the first American factories imported all their machinery, some of the machines used are now made exclusively in America, and some of the best factories have no imported machinery.⁵ In some cases foreign machinery has been found unsatisfactory and inferior to that made in America.⁶ It was at first necessary to employ experts from abroad to operate the machinery, but as Americans have learned the processes the amount of foreign labor has diminished.⁷

The producers of about one-half of the sugar beets grown in Germany own shares in the factory in which the sugar is manufactured. The inauguration of a similar system of cooperation is recommended in this country as a means of preventing misunderstandings between the manufacturers and the beet growers.⁸ A large share of the stock of the Holland Sugar Company, Michigan, is owned by the farmers of the vicinity.⁹

Cane sugar.—It is thought that Louisiana is not far enough south for cane sugar, though it is too far south for beet sugar, and that the production of cane sugar in the United States is likely to diminish. The cost of producing sugar in Louisiana is considerably higher than farther south. Cuba, Hawaii, and Porto Rico are characterized as natural cane-producing countries.¹⁰ It is estimated that fifty years hence, under favorable conditions, Cuba may produce three million tons of sugar a year. Hawaii exceeds Cuba in the yield per acre, but nearly all the land in Hawaii capable of growing sugar is already under cultivation. Sugar cane is not thought to be susceptible of scientific improvement to the same extent as sugar beets.¹¹

The size and capacity of the Louisiana sugarhouses have been greatly increased during recent years, and it is found that sugarhouses with a capacity of 1,500 tons of cane daily produce sugar much more cheaply than those of 200 tons capacity, requiring no more expert labor. Part of the residual molasses is fed to stock, but as the amount produced is much greater than is needed for that purpose in the vicinity of the sugarhouses, the remainder is mixed with glucose and sold as Louisiana sirup.¹²

Maple sugar.—Maple sugar is produced to some extent in about half the States of the Union, but its production is greatest in Vermont, New York, and Ohio, in the order named. In Vermont the maple-sugar industry is as important as anything the farmers are engaged in, with the exception of dairying, bringing them an income of from \$1,000,000 to \$1,500,000 a year without interfering with their

¹² Stubbs, 774, 775.

other products, since the sugar season comes at a time of the year when there is not very much else to be done.¹

Consumption and production of sugar.—The annual consumption of sugar in the United States is estimated at about 2,000,000 tons, of which nearly 1,700,000 tons are imported. Three-fifths of the sugar consumed in the country is beet sugar. Of the total world's production of sugar more than half is produced from beets, nearly all the beet sugar being made on the continent of Europe. The demand for beet sugar increases at a very rapid rate, the annual increase for the past 30 years being 13 per cent. It is therefore estimated that this country will be able to consume all the sugar it can produce, including that produced in the insular possessions, for at least a long time to come. A beet-sugar factory such as that at Binghamton, N. Y., produces less than one-third enough sugar to supply a city of 50,000 inhabitants. In 1898 the production of beet sugar in the United States was about fifty or sixty thousand tons, while the imports of foreign beet-sugar amounted to 800,000 tons. Dr. Wiley goes so far as to say that the admission duty free of every pound of sugar made in Porto Rico, Cuba, and the Philippines would not affect the progress of the sugar-beet industry in this country, for there would still be a deficit to be supplied. While the cost of producing beet sugar in this country has thus far been somewhat higher than the cost of producing sugar in Germany or Porto Rico, Dr. Wiley predicts that when the industry is well established, with the advantages of superior American machinery and cheap fuel economically used, the cost of production will be almost, if not quite, as low in this country as in Europe, in spite of the greater expense for beets and for labor. He says that in the cultivation of the beet we are still far behind Europe. The low cost of labor is said to be the only great advantage of Porto Rico, Cuba, and Hawaii in sugar production, and attention is called to a tendency toward increased wages in those islands. Mr. Saylor believes that the cost of production will increase in all the islands named and constantly decrease in the United States proper.²

Some fears are expressed, however, of the effect of the admission of sugar free of duty from the insular possessions of the United States, especially before the industry is well established in this country. It is pointed out that the sugar production of Hawaii increased greatly after the reciprocity treaty of 1876, and that if the production of the Philippines should increase in anything like the same proportion they could supply the entire demand of this country.³

Cane and beet sugar compared.—While no chemical difference between cane and beet sugar has been discovered and it is impossible to distinguish between them in ordinary table use, beet sugar is said to be inferior to cane sugar for preserving, and it is predicted that that will be the chief use for cane sugar in the future. Another difference is that beet sugar must be absolutely pure before it can be used, while cane sugar is good even before it is refined.⁴

It is predicted that the United States will eventually make its own sugar, mainly, if not entirely, from beets.⁵ To produce the sugar consumed in the United States would require devoting more than a million acres to sugar beets, with the result that this area would be taken out of competition with other agricultural products, while the money now sent abroad for sugar would remain at home, and employment would be given to the unemployed.⁶

Sugar refining.—Nearly all the beet-sugar factories in the country are independent of the American Sugar Refining Company, being equipped to make refined sugar. It is apparently profitable for a factory to refine its own sugar when the difference between the prices of yellow sugar and granulated sugar is more than one-half cent, the expense of refining being slight. When the difference has

fallen below that amount, as in 1899, the Binghamton Beet Sugar Company has sold its entire product to the American Sugar Refining Company.¹ Most of the Louisiana sugarhouses are also prepared to refine sugar when the price of unrefined sugar is unsatisfactory.²

OBSTACLES TO SUCCESSFUL AGRICULTURE.

Insect pests.—Dr. Howard gives a systematic account of the ravages of insect pests and the efforts of economic entomologists to abate them. Injurious insects have been a drawback to agriculture as long as men have cultivated crops, but as agriculture has become more extensive the conditions have become more favorable for the rapid multiplication of insects. It is more difficult to exterminate an insect pest in a large field than under a system of intensive culture. The annual loss to this country from injury to crops by insects is estimated at about \$300,000,000, and there is also some injury to live stock caused by insects. It has been estimated that the loss would be twice as great as it is if it were not for the work of the economic entomologists. Over against the saving effected in this manner is an expenditure of \$30,000 a year by the United States Government and of various amounts by 30 States which have State entomologists. There is now a fairly good remedy for every insect of importance, although at the time of the foundation of the Department of Agriculture not a single reliable remedy was known for any insect pest. Spraying with petroleum or an arsenical solution is often employed, especially for scale insects. For the San Jose scale a wash of lime, sulphur, and salt is used in California in dry weather, while in the East a strong solution of whale-oil soap is often used. As most injurious insects are themselves subject to the ravages of parasites, the entomologists have imported from Australia and other countries a number of these parasitic insects, and have also propagated fungous diseases with which to destroy injurious insects. The damage done by the clover-seed midge is prevented in Ohio by cutting the clover a week or two earlier than was formerly customary. Certain other pests are kept away from the crops they formerly injured by concentrating them upon "trap crops" of cow-pease, corn, etc. The banding of trees is useful in some cases, but most insects which infest shade trees are strong flyers in the moth stage, so that banding is not an effective protection against them. Birds are an important agency in keeping injurious insects in check, and the shooting of birds therefore increases the chances for the multiplication of insects, though some species of birds are much more useful than others in this respect.

It is a significant fact that a majority of the important insect pests prevailing in this country have been imported from abroad. Thus the Hessian fly is supposed to have been introduced in the straw bedding of the Hessian soldiers in the Revolutionary war; the San Jose scale is thought to have been brought to California from Japan; the gipsy moth was imported by a scientist in an attempt to improve upon the silk worm, and the hop-plant louse and other injurious insects have found their way into this country on imported plants. Twenty-one States have inspection laws for nursery stock and other plants brought from outside their borders, to prevent the introduction of injurious insects; but the lack of uniformity in these laws makes it necessary for the nurseryman who ships stock to different States to consult the provisions of the different laws. The desirability of uniform State legislation is emphasized, and the quarantine law of California is mentioned as a model law in most respects. At the port of San Francisco every incoming vessel is boarded by an officer who examines any nursery stock or other vegetables the cargo may contain, and fumigates or destroys any which are infested, if consigned to points in California. But the California law does not prevent the ship-

¹ Wiley, 655; Rogers, 553, 559.

² Stubbs, 771, 772.

ment of infested material to points outside the State; hence when the inspector finds infested plants consigned to other States he notifies the Chief Entomologist of the United States Department of Agriculture, who in turn notifies the proper officers of the State concerned; but in some important States the State officers have no authority to require inspection of the plants on their arrival.

The desirability of uniform legislation is especially urged because of the lack of any national legislation for preventing the spread of insect pests. A national quarantine bill has been before Congress at several sessions and has been favorably reported by the House Committee on Agriculture. It provides that the Secretary of Agriculture shall have power to quarantine against any country from which injurious insects are likely to come, and also to designate certain ports at which nursery stock must be imported, where it will be subjected to inspection if not accompanied by a certificate showing that it has already been inspected. The bill also provides for the regulation of interstate traffic in nursery stock, etc. The bill was at first opposed by the nurserymen, but it is strongly favored by California fruit growers, especially as a means of prevention against the Mexican orange maggot. A committee of the American Association of Nurserymen has submitted a memorial in favor of the bill, which has also been indorsed by entomologists and vegetable pathologists. It is estimated that the cost of such a quarantine service during the past 30 years would have resulted in saving to the agricultural and horticultural interests one hundred times its cost.¹

Diseases of animals.—While the animal industry in the United States has suffered from hog cholera, sheep scab, Texas fever, and other animal diseases, it has been more fortunate than in many European countries in escaping such plagues. Pleuro-pneumonia was quickly eradicated by the Bureau of Animal Industry, in cooperation with State authorities. Foot-and-mouth disease has also been eradicated each time it has been introduced, and rinderpest has never reached this country. The loss from glanders and hog cholera is as great as ever, and tuberculosis in cattle is becoming more and more common. In States lacking proper regulations herds of cattle are frequently found to contain from 80 to 90 per cent of tuberculous animals, and the general average among dairying and breeding cattle is estimated at about 5 per cent.² While it is still disputed whether tuberculosis can be transferred from cattle to human beings, cases are reported in which there was at least strong presumptive evidence of such infection.³ The cooking of meat renders infection through that source unlikely, but it seems probable that the use of unsterilized milk from a cow in which the disease has attacked the milk glands may result in disease in human beings, especially children.⁴

Trichinae are said to be found in American pork in a greater percentage of cases than in most other countries. Two per cent or more of the hogs sent to market are infected, and in some consignments 25 or 30 per cent have been found with trichinae. The prevalence of these parasites is attributed to the practice of allowing hogs to eat dead animals, such as rats, mice, and the carcasses of other hogs, which is due partly to the popular impression that the feeding of meat lessens the losses from cholera.⁵

The comparative exemption of this country from animal diseases is attributed to the newness of the country and the free access of the animals to pure air, some diseases, at least, being generally confined to animals kept in stables.⁶

Serious difficulties are met with in the enforcement of State laws for the suppression of animal diseases. It is claimed that there is scarcely a Jersey cow in the State of New York that will not respond to the tuberculin test used for the detection of tuberculosis, and when diseased cattle are condemned it is said that

their owners sometimes get more from the State than they are worth.¹ The compensation paid in such cases is sometimes limited either to one-half the value of the animal or to a fixed sum for an animal of a given class.² The suggestion is made that laws against animal diseases can be better enforced by the State agricultural departments than by the State boards of health, because veterinarians and live-stock experts know better what is needed than regular physicians.³

The State laws do not always authorize the executive officers to do all that is necessary to prevent the spread of disease. Thus the New York Department of Agriculture is authorized to suppress foul brood in bees, but has not been authorized to deal with black brood, a similar disease which has recently made its appearance. Generally speaking, the State authorities are perhaps at some disadvantage as compared with the Federal authorities in enforcing unwelcome regulations, partly because of the difference in the feeling of the people toward the two sets of officers. Dr. Salmon lays down the principle that the nearer the government is to the people the harder it is to enforce such laws.

There is much difference between the laws of the various States in the matter of compensation for destroyed animals, as well as in other respects. Veterinarians are disposed to favor the payment of compensation, because it is found to be cheaper to pay compensation and secure the cooperation of stock owners in detecting disease than to make it to the interests of the owners of animals to conceal the disease.⁴ It is suggested that when tuberculosis is far advanced no property right in the animal should be admitted to exist, but that in milder cases a payment ought to be made proportioned to the value of the animal, taking into account the stage of the disease.⁵

The State laws for the prevention of glanders in horses are considered insufficient.⁶ Attention is called to the need of better State control of such diseases as glanders, tuberculosis, and rabies, of State laws prohibiting the feeding of carcasses of dead animals to swine, and also of measures to insure the wholesomeness of the milk supply and better local inspection of meats and the proper disposition of diseased meat. At present boards of health seldom have the authority or means to inspect the stables in which dairy cows are kept, and aside from the danger of contagion through milk there is a likelihood of digestive derangements from a contaminated milk supply. It is important to insure clean stables and careful handling of the milk, as well as healthy cattle, and it is suggested that this control would be most effectively secured by uniform regulations applied to the dairies of entire States. It is said that few cities, if any, have a sufficient force of competent meat inspectors to protect their cities from disease from unwholesome meat. The natural effect of the Federal inspection has been to drive the diseased animals to abattoirs which slaughter for local consumption.⁷ It is suggested that the expense of meat inspection be made by a charge for all meat inspected. It is questioned whether it is practicable to meet the expense by fines, partly because when the prescribed fines are heavy judges hesitate to impose them.⁸

Food adulteration. (See also Vol. XI, Part VI.)—While the adulteration of food is not of recent origin, it has been greatly increased with the modern development of commerce.⁹ It is estimated that 15 per cent of all food and drug products are fraudulently adulterated, and that 2 per cent are so adulterated as to be injurious to health.¹⁰ The prevalence of adulteration is attributed to two causes: (1) the stress of competition, and (2) the need of preserving certain foods against

decay.¹ A variety of injurious effects, not only physical, but also moral and financial, are attributed to food adulteration.² Several witnesses point out that the farmer is especially injured by food adulterations, even when the materials used for adulteration are agricultural products, because of the tendency to impair confidence and so diminish the sales.³

One of the most dangerous forms of food adulteration is the sophistication of milk, which appears in its most common form in the removal of the cream. This skimming of milk takes away the greater part of its food value. This matter is sometimes regulated by law or ordinance, and it has been found in Chicago that publishing the names of those whose samples were found below grade resulted in a great improvement in the character of the milk offered.⁴

It is complained that the New York State brand for full cream cheese has been imitated by dealers in the West and placed on inferior goods; and this illegitimate use can not be prosecuted under the trade-mark laws.⁵

It is believed that the mixed-flour law has resulted in the almost complete abandonment of the mixing of corn flour with wheat flour.⁶

Carelessness in the preparation of food sometimes results in extraordinary uncleanness. One witness exhibited a piece of bread with a young rat baked in it.⁷

Complaint is made that the prepared foods sold for live stock, as well as for human beings, are sometimes so adulterated as to be of very little value.⁸

Oleomargarine.—There are differences of opinion as to the wholesomeness of oleomargarine when properly manufactured. Two witnesses regard it as a good food,⁹ but two others regard it as unwholesome. It is pointed out that while the butyric acid of butter is an aid to digestion, oleomargarine is difficult to digest because of the large percentage of stearin.¹⁰

THE MARKETING OF FARM PRODUCTS.

The securing of a market is declared to be the all-important question to the farmer, for without a market a large production represents only a loss to the extent of its cost. Attention is called to the importance of statistical information concerning production and consumption of farm products as a means of maintaining a reasonable equilibrium between supply and demand and assuring a profit to the producer. There is often an overproduction of some particular crop for lack of such knowledge.¹

Where the price of wheat is fixed.—Several witnesses agree that the price of wheat is fixed at Liverpool, the chief wheat market of the world, and that although only about 10 per cent of the wheat produced in this country is exported the export price determines the price of the whole, that remaining within the country being sold at the Liverpool price minus the expense attending transportation to Liverpool.² The price at Liverpool, however, is governed by conditions in all parts of the world,³ and is affected by the cheap labor of India, Africa, and Russia.⁴ Mr. Powers maintains that the markets of the world are dominated by the products of American farms, and are determined by the cost of production and transportation. He says the farmer who can produce large quantities of grain cheaper than the rest of the world does more than anyone else to fix the price,

and that the price of wheat is determined by the small farmer of the West, who with a system of diversified farming works three hundred days in the year, rather than by the farmer of Argentina or India, who works only sixty days in the year.¹

Cost of transportation.—There appears to have been a decline in the cost of distribution of agricultural products during the latter part of the century, especially where long-distance transportation was involved. It is stated that in the early seventies the cost of sending a bushel of wheat from Iowa to Liverpool was equal to the cost of producing from 1 to 2 bushels, while at present the cost has been reduced to little more than half the cost of a bushel.² The freight rates from the West to the Eastern part of this country also show a marked diminution.³ Local freight rates in the East show comparatively little change, and in some cases an increase of rates is reported. There is also complaint that farmers in the eastern part of Ohio are compelled to ship their grain west to Toledo before it can be shipped East.⁴

There are complaints of excessive freight rates in the South, both on cotton and on vegetables and fruits. A Memphis cotton broker says there would be a great outlet for cotton in the Carolinas if it were not for the prohibitive freight rates, which are higher than the rates to New York, or even to Lowell. The high cost of transportation to the North is said to be the great difficulty about going into truck industries in the South.⁵

Georgia fruit-growers say that they pay more in proportion to the distance than California shippers, but complain especially of excessive rates charged after the fruit reaches Northern roads.⁶ On the other hand, California fruit-growers say that they can not put their fruit into New York City as cheaply as Florida fruit growers can, and that in general freight rates from California to the East are excessive, being the same now as in the infancy of the traffic, except where there is effective water transportation, though the cost of operation has declined. California fruit does not get the advantage of water competition because it is necessary to send it by rail.⁷

Opinions differ as to whether reductions in freight rates accrue to the advantage of the producer or only reduce prices to the consumer.⁸

Shipment of fruit by express.—Fruit growers complain that it is necessary to have an entire carload in order to ship in refrigerator cars, and that the shipment of smaller quantities by express costs fully three times as much as shipment in refrigerator cars, the difference between the two rates being more than the profit. This is declared the greatest drawback to the small fruit grower. Several West Virginia fruit-growers, however, have arranged to make joint shipments in carload lots.⁹

Transportation facilities.—A general improvement in transportation facilities, especially a shortening of the time required for freight shipments to reach their destination, is reported both from the Northwest and from the South.¹⁰

California fruit-growers have suffered from an insufficiency of transportation facilities, which caused delays in shipments of their fruits, but ample facilities have been promised in the future.¹¹

California fruit is shipped in refrigerator cars, operated by car lines under contracts with the railroads, and complaint is made of excessive refrigerator rates. It is estimated that altogether the carriers get about one-half the gross proceeds from sales of California citrus fruits.¹²

Railroad pools.—There appears to be a pooling arrangement in force between the railroads which carry cotton and cotton goods from Memphis to Eastern ports, each road being allowed a certain percentage of the traffic. This pool has been attacked in the courts, but the Supreme Court of Tennessee has declined to interfere.¹

A somewhat similiar division of business is in force between the railroads which ship fruit East from California.²

Railroad discriminations (see also Vols. IV and IX).—Complaints are made of railroad discriminations both between different localities and between different classes of freight,³ and also of discriminations between shippers in the form of special rates and rebates.⁴ The interstate-commerce law is said to have been hailed with pleasure by the railroads because it simplified their business; they prefer to give a rebate to one man rather than to 100 or 500.⁵

There are numerous complaints of the inefficiency of the interstate-commerce law, especially in preventing discriminations.⁶

The farmers and the middlemen.—Mr. Holmes points out that farmers are so numerous that they are subjected to severe competition with one another in disposing of their products, and hence are at the mercy of the middlemen, being compelled to accept whatever price is offered. The position of the farmer is thus economically weak. Mr. Holmes recognizes the necessity of the middlemen, but would like to see the farmer become his own middleman.⁷ It is suggested, however, that even if farmers were to choose men of their own class to buy and sell for them these agents might be no better than the original commission men.⁸

The introduction of organization and business methods in the marketing of crops is thought to be an important means of improving the condition of the farmer, and the success of the truck industry at Norfolk is attributed to the organization of the growers through which they place their crops in certain markets according to the demand, as shown by daily market returns from different cities.⁹ Another instance of cooperative distribution is the Milk Producers' Union which supplies Boston with milk. Representatives of this organization meet every year with representatives of the Boston Milk Dealers' Union and agree upon prices.¹⁰ An attempt has also been made to organize the dairymen supplying New York city with milk. A similar effort in Philadelphia is reported to have been a failure.¹¹

Some of the most successful instances of cooperative distribution are found among the fruit growers, especially in California, though cooperative marketing of fruit has also been developed along the Atlantic coast. The Southern California Fruit Exchange is a cooperative organization receiving citrus fruits from local exchanges at various points and marketing them through its own salaried agents throughout the country. While the prices to the consumer have probably not increased, the prices received by the producers are better and the losses smaller than under the commission system formerly prevailing, which was found to be unsatisfactory. California cured fruits, such as prunes and raisins, are marketed by other cooperative organizations somewhat similar to the Southern California Fruit Exchange, except that they attempt to sell at a certain price *f. o. b.* California, instead of selling through agents at the prices prevailing in different markets.¹²

Local markets.—The importance of home markets to American farmers is emphasized by a number of witnesses. It is pointed out that the prices of articles

which are not exported, such as eggs, butter, and vegetables, are fixed in this country—not in Liverpool, as the price of wheat is, in competition with the cheap labor of other countries—and that by reason of the development of manufacturing, mining, and transportation, and the increasing city population, the farmers, especially those who produce vegetables, poultry, dairy products, fruits, etc., have an increasingly valuable home market. It is suggested that the relief of agriculture must come partly through an increased consumption of luxuries, such as fruits, which represent a relatively large amount of labor, and that the increased demand for these luxuries in the United States is of as much importance to the farmer as increased exports. In Minneapolis fruit sales are said to have doubled once in three years, or eight times as fast as the population.¹

Speculation.—It is explained that speculation in grain has a legitimate function, and is a good thing if the buyers are on an equal footing with the sellers, because when the price gets too low some one will take the grain as an investment, and this will tend to check the fall in price.² Several witnesses are of the opinion that corners in wheat, such as that of 1898, are an advantage to some of the farmers.³ The sale of fictitious grain, however, is considered an injury to the farmer. When large quantities of grain which do not really exist are offered for sale, it is thought that foreign markets may be influenced by creating an impression that there is actually a large supply, so that grain may be sold at prices lower than the supply would warrant. It is said that warehouse and insurance charges are often paid on fictitious grain, and that the burden must ultimately fall on the farmer. The fact that the prices of oats, corn, and barley are more satisfactory than the prices of wheat is explained by their comparative immunity from fictitious sales. It is pointed out that the sale of great quantities of wheat for delivery at future dates makes it necessary for those who have to deliver the wheat to attempt to keep the price down. Mr. Dye expresses the opinion that grain and cotton gambling is injurious both to the producer and to the consumer.⁴ Some witnesses condemn dealing in futures generally, without distinguishing between bona fide and fictitious sales.⁵ In particular, it is charged against speculators that their activities tend to depress prices at and after the time of harvest, from September to about January, when most of the farmers are compelled to sell their grain.⁶ Another charge against speculation is that though it may have a steadying effect on prices, it demoralizes cotton planters by leading them to speculate, and that the people of the South lose large sums of money by betting on cotton.⁷

Seasonal fluctuations of prices.—Statistics appear to show that the price of wheat is usually lower for three or four months after harvest than at other times, but in considering the advisability of holding wheat for higher prices allowance must be made for interest on its value, damage by mice and rats, shrinkage, etc. It has been calculated that by buying cash wheat September 1 and holding it until May one would lose, on the average, 2 cents a bushel, the boards of trade in the Northwest usually having their prices in the fall a little higher than the situation really justifies. The Minneapolis millers seem to realize that the fluctuations in the price of wheat would, in the long run, cause them more loss than gain, and so protect themselves against loss by selling a future against grain when they buy it. The best time to sell grain appears to be immediately after thrashing, at least for the farmers who get to market first, though it is suggested that there is a better

XLVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

chance of gain by holding grain until the following summer than by holding it for a shorter time. One witness, however, remarks that farmers generally will not sell while prices are going up, but wait until they go down.¹

In the case of cotton, also, the average price is lowest between cotton-picking time and the 1st of January, when the bulk of the crop is marketed. The Southern practice of giving crop mortgages forces the greater part of the cotton into the market within a short time in the fall. It is estimated that 90 per cent of the farmers of Georgia are compelled to sell their cotton at that time. There is evidence, however, that even planters who are not pressed for money market their cotton in the fall rather than take the risk of storing and holding it.² One witness thinks the prices are as good at the beginning of the season as later.³ Another expresses the opinion that speculation on the exchanges has no effect on the price of cotton.⁴

ELEVATORS.

In the Northwest.—Bitter complaints are made of combinations among the grain warehousemen, not only at such important transfer points as Chicago and Buffalo, but also throughout the wheat-growing region of the Northwest. Some witnesses claim that there is no monopoly among the Northwestern elevators, since more than one company is usually represented in each town of importance; but it is not denied that the elevators along a given railroad often form a system or "line" owned by one company, and there is abundant evidence of an understanding between the different elevator companies regarding the prices to be paid for grain.⁵ It seems that the price of wheat for the territory tributary to Minneapolis is fixed by a board or committee in which the Minneapolis Chamber of Commerce, the elevator men, and the commission men are represented. Any increase or diminution in the price of wheat is telegraphed to the representatives of the elevator companies at the principal towns, who in turn send out postal cards to the smaller places, or in some cases send the prices by telegraph or telephone, if so instructed from Minneapolis. It is alleged by one witness that when the price goes up the notice is sent out from Minneapolis by mail instead of by wire. The elevators endeavor to keep the price of wheat to farmers about 3 cents (plus the freight) lower than the cash price of wheat on track in Minneapolis.⁶ It is explained, however, that neither the elevator companies nor their buyers are bound by the card prices, but that they pay more than the card price for wheat of especially good quality, or when it is necessary in order to get the wheat.⁷

It is alleged that the elevator companies have discriminated between localities in buying wheat by grading the wheat too low at a given place.⁸ There is said to be a community of interest between the railroads and the elevators, though their operation is entirely distinct. The northwestern elevators were originally built either by the railroads or railroad officials, or by large shippers of grain; but they are not thought to be owned at present to any great extent by those who control the railroads.⁹ The system of railroad rebates to the elevators, which is said to have been general at one time, is thought to have been discontinued, at least on the Great Northern Railroad, at noncompetitive points, but is believed to be still in existence where there is competition; but even those who are closely connected with the shipping of grain are unable to ascertain definitely what the facts are.¹⁰ One instance is reported in which the proprietor of an inde-

¹⁰ Prom, 800, 801; Jumper, 737.

pendent elevator is said to have received a rebate in the form of a check for labor which he had not performed.¹

Independent shipments.—In order to avoid the alleged oppression of the elevator combination the farmers of the Northwest sometimes ship their grain independently, consigning it to commission merchants in Minneapolis or Duluth, who sell it for what it will bring. There is said to be a decided advantage in doing this, at least with wheat of unusually good quality. In some cases, where shipments have happened to be made on rising markets, farmers have made \$50 or \$60 a car by shipping independently. Difficulty is sometimes experienced in getting cars for these independent shipments, but this is, perhaps, because the elevator companies have ordered cars in advance of the private shippers. Shippers are said to be more apt to get cars at competitive points than elsewhere.²

Farmers' elevators.—As another means of securing independence from the line elevator companies the farmers of the Northwest have organized stock companies and built a large number of independent elevators in Minnesota and the Dakotas. These elevators are under some disadvantage in having no connection with a terminal elevator at Minneapolis or Duluth, but they ship to commission merchants. The farmers' elevators allow a margin of only 2 cents for operating charges. These independent elevators have sometimes had difficulty in securing sites on the railroad right of way, especially at noncompetitive points, but the Great Northern Railroad now allows them sites, and other roads have been obliged to do the same.³ South Dakota has a law compelling the railroads to give these facilities to independent elevators on the same terms for ground rent as to line elevators.⁴ It is charged that the line elevators actively oppose the independent elevators by outbidding them for wheat until they are driven out of business, after which the loss is made up by lower prices.⁵

Grain inspection in Minnesota.—There is some complaint about the grain inspection at terminal points in Minnesota. This is said by one witness to be the greatest evil from which the farmers of North Dakota suffer. It is alleged that the grades given North Dakota wheat are too low, and that the grain inspectors are unduly influenced by the elevator men.⁶ Mr. Prom suggests that the appointment of inspectors should be taken out of the hands of the Governor of the State, and that the inspectors should be appointed for their fitness and allowed to appoint their own deputies. As a still more thoroughgoing remedy it is proposed that a system of interstate inspection be established by the States of North and South Dakota, Minnesota, and Wisconsin.⁷

The Chicago elevator system.—Even more definite charges are brought against the Chicago elevators than against those in Minnesota and the Dakotas. There appears to have been little difficulty in the handling of grain in Chicago between the enactment of the Illinois railroad and warehouse law of 1871 and about 1887. It is said that prior to the passage of the interstate-commerce law rebates were given to individual shippers to bring grain to the Chicago market, but that the

⁴ Jumper, 736.

⁵ Moran, 717; Prom., 798, 799.

⁶ Mr. Teisberg, secretary of the Minnesota Railroad and Warehouse Commission, expresses the opinion (Vol. IX, p. 371) that there is no combination among the Minneapolis elevators, and that the price of wheat sent out daily is merely the closing quotation for the day. Many independent elevators have been established in Minnesota under a State law providing for the condemnation of sites on railroad rights of way for elevator purposes; and farmers can often load their grain directly into the cars. Mr. Teisberg also discusses the Minnesota system of grain inspection, and denies that inspectors are unduly influenced by the warehousemen. (Ibid., pp. 368-371.)

⁷ Prom, 799, 801.

passage of that act made it necessary for the railroads to give rebates more cautiously, and that they chose the public warehousemen as the ones to be favored. Within a few years the system of handling grain in the Chicago elevators changed, and the elevators passed into the hands of persons who at once embarked in the business of dealing in grain, the proprietors of the warehouses being now the most extensive grain dealers, and owning a large part and in some cases all the grain stored in their elevators. The chief advantages of the warehouseman in competition with the public are said to be (1) that he pays no storage on the grain, or pays storage to himself, so that the possession of the elevator operates as a rebate; and (2) that he is able to select the best grain of a given grade and keep it for himself as merchant, giving the public the "line" grade, or grain just good enough to pass inspection. The result has been that the public is unable to compete with the elevator managers, so that grain going to Chicago elevators finds but one buyer—the elevator proprietor.¹ It is declared that there is a grain monopoly in Chicago, the elevators acting together and demanding premiums on the wheat they sell. Most Chicago elevators are said to be owned by the railroads and leased to the warehousemen under an agreement that the lessees are to pay so much a car for all grain going through the elevators.² The accumulation of grain in Chicago for the purpose of earning storage charges is said to have resulted in such a congestion as to depress prices. It is explained that when a warehouseman gets possession of grain he sells it ahead for future delivery, so that some one else pays storage charges on it, then waits for the buyer to sell out, and stands ready to take the grain back and sell it ahead again. This is said to have produced an endless chain of forced liquidation on the part of the buyers.³ It is charged that in 1894 the elevator proprietors sent buyers into the country and brought large amounts of grain to Chicago, solely for the purpose of making it earn storage. This swelled the visible supply to such a great extent as to depress prices in the markets of the world, besides throwing the grain into the control of the elevator interests.⁴

These practices on the part of the warehousemen,⁵ while they are said to result

⁵ A large amount of testimony concerning the Chicago elevators appears in the first volume on Transportation (Vol. IV.). The evidence is clear that the great terminal elevators at Chicago, and to a less degree in other grain markets, are owned by comparatively few men or firms; that the owners of public elevators, where grain may be stored at fixed charges by any holder, also control great private elevators; that they themselves buy a very large proportion of the grain which comes into the public elevators; and that the business of handling grain on commission has been very greatly reduced by this practice. The elevator owners admit that they are very large buyers of grain. It is claimed by their opponents also, although the evidence is less definite, that these same owners of terminal elevators own or control most of the country elevators and warehouses; that in fact practically all the elevators along the lines and at the terminals of each railway system are in the hands of a single organization.

The opponents of these large dealers admit that the elevator owners pay more for grain to the local dealers and farmers than the commission merchants and small dealers can pay, but they declare that this is due to various unfair advantages. Thus, the elevator owners themselves are exempt from the terminal storage and transfer charges which must be paid by other persons—three-fourths of a cent for transfer and the first 10 days' storage—which is alleged to be much more than the actual cost. It is further declared that the elevator owners receive great advantages from the railways in the forms of allowances for handling grain and of direct freight discriminations. In fact, it is held by many witnesses that the railway companies or their officers are largely interested in the elevators and in grain buying. The evidence as to discriminations in favor of the elevators is chiefly indirect, based either on general belief or on the known fact that the elevator owners often pay more for grain at country stations than the price at Chicago, Kansas City, or Milwaukee, minus the full freight rate, would warrant. The excess in the price offered was shown to be sometimes as high as 2 or 2½ cents on both wheat

in the greatest damage to the farmers by the depression of prices,¹ are complained of most bitterly by Chicago grain dealers, who say that Chicago has been greatly injured as a grain market, and that the grain is now going to other points, the amount shipped from Chicago growing less year by year.²

It is pointed out that when a man is custodian both of his own grain and of other people's at the same time, he is subjected to great temptation to manipulate the grades and weights.³ It is said that the warehouseman can by mixing two cars of No. 2 wheat with three cars of No. 3 make five cars of No. 2 wheat.⁴ The mixing of grain has become so important a matter that nearly every terminal elevator in Chicago has a mixing house connected with it, in which grain of high quality is mixed with that of a lower grade to bring it down to the lowest point at which it will pass in the same grade as before. One case is mentioned in which a warehouseman called for reinspection of 50 cars of corn, in order to have it sent into his elevator at a lower grade and have it inspected out at the original grade.⁵

Complaint is made that elevator proprietors are able to exercise espionage over the business of other dealers in grain and flaxseed.⁶ Complaint is also made of

and corn. It is also stated that in 1890 a rebate of 5 cents per hundred was proved before the Interstate Commerce Commission to have been granted to certain elevator owners.

It is also alleged that the Eastern railways have largely leased their transfer elevators to private companies which also deal in grain, and that the charges made by these companies are excessive, so that they have an advantage over competitors.

The elevator owners deny that the charge of three-fourths of a cent for handling grain is excessive; the law permits 14 cents to be charged, while the actual charge is the lowest known anywhere. They deny also that the railways operate elevators directly, or, in the cases where they own them, have given special favors in leasing them to the present operators; though no very detailed evidence is presented. Mr. Webster, of the Armour Elevator Company, claims that that company actually owns most of its numerous elevators and pays high rentals for the remainder, while Mr. Counselman declares that the elevators on the Rock Island were built and paid for by his own firm. Mr. Webster also denies that the elevator owners receive discriminating rates from the railways.

In view of the quite general acknowledgment among railway men that discriminations in favor of large shippers are still conspicuous, there seems to be a considerable probability that the claim that these large elevators receive favors from the railways, in one way or another, has some basis.

The elevator men explain further the reason for their buying grain and for their advantages over competitors. They claim that the establishment of through rates on grain from the Mississippi River and other Western points to the seaboard lower than the sum of the local rates from those points to Chicago and from Chicago east gave an advantage to Eastern commission merchants and buyers, so that Chicago elevator owners found it necessary to buy grain on a large scale and handle it in the same way, on through rates, in order to keep their warehouses from standing idle. Moreover, the competition of the newer markets of the West forced these men to buy grain to protect Chicago as a market. The advantages which have made it possible for them to compete successfully with other markets, and largely to take business away from commission merchants, arise from their large capital, which enables them to carry large quantities of grain in anticipation of favorable markets, from the elimination of commission and other intermediate charges, and from the ability to forego a part or all of the normal charge for actual elevator service. The elevator owners have the same advantage over commission merchants that any business man who furnishes himself with all accessory materials and facilities, instead of obtaining them from others, especially from his competitors.⁷ One or two witnesses, however, claim that, as regards local buying, the small dealer, who has perhaps other business during the season when there is little grain buying, can handle the grain business more cheaply than a great concern.

Effect on prices.—The opponents of the elevator owners declare that there is a growing monopoly of the local elevators; and that while there is still competition at times, and while in such cases the large buyers pay the higher prices, sooner or later all competitors will be driven out and the farmer will be at the mercy of the great elevator owners. It is maintained, moreover, that where different elevator owners operate along the same line of railway they do not actively

fraud in the dating of warehouse receipts. In 1896 the Chicago Board of Trade investigated a case of this kind in which charges were filed against four persons, and the one who assumed the responsibility was suspended from the board.¹

Abuses in the Chicago grain market.—Various other abuses are complained of in connection with the Chicago grain market. Thus it is said that bills of lading issued by transportation lines do not comply with the statute of Illinois requiring that grain received for transportation shall be correctly weighed and a bill of lading issued stating the true weight, and requiring the company to deliver the amount of grain without deduction for leakage, shrinkage, etc. In practice the weight column is headed "Weight, subject to correction," or some equivalent expression, and the final weights are determined in Chicago. The shipper is thus obliged to accept the railroad's statement as final. There is said to be an average shortage of three or four bushels to a car, and in some cases the shortage has been as high as 20, 25, or even 100 bushels. The shippers do not institute legal proceedings to protect their rights for fear of aggravating the railroads, and so getting into further trouble.²

The growing system of the ownership of private cars by individuals and corporations is severely condemned.³

compete, but meet daily on the Chicago Board of Trade and agree as to the prices which they will pay, at least as to certain territory. No evidence is presented to show specific cases where prices have been depressed by elevator owners.

To these charges the elevator owners reply that, at least along many railroads, they do not control any large proportion of the local elevators. They buy largely from the local dealers, who compete among themselves; and there is nothing to check the competition of the different elevator concerns. There are few railroad stations which do not have two or more buyers. No agreement exists for limiting competition or fixing prices, except that certain leading Chicago elevator men do discuss daily the prices which they will pay in Kansas and other parts of the West, where the Chicago market comes into severe competition with other grain markets. The purpose is to agree upon a price high enough to bring the grain to Chicago. At practically all stations local dealers receive daily bids for their grain from a large number of buyers—often from 5 to 20. The existence of these competing bids is admitted by some of the opponents of the elevators.

Two country grain dealers from Iowa and Nebraska also testify that in their towns there are competing grain buyers, and that each of the local dealers receives bids directly from various elevator owners at Chicago and also from other markets, there being often a considerable range in the prices offered.

The elevator owners maintain that the farmers are not only not injured by the existence of these large buyers, but that they are benefited by the elimination of various commissions and profits which were formerly paid by grain in its progress from the producer to the consumer, and by the many economies which elevator owners are able to effect. The elevator owner is satisfied with a little profit on a large business.

The two local grain dealers referred to above also declare that the farmer benefits by the elimination of middlemen under the present practice. Moreover the reduction of the risk borne by the local dealer, from the fact that he receives bids for his grain on track every day, enables him to work on a narrower margin.

Apropos of the claim that certain warehouses have taken advantage of other grain dealers by delivering the poorest quality of grain which will meet the official grade and keeping the better qualities, it is declared by a representative of a prominent milling company that millers are forced to disregard official inspections in order to prevent the warehousemen from giving them inferior qualities. The elevator owners, on the other hand, declare that their practice of mixing and cleaning grain for the purpose of improving the grades is beneficial to all concerned, that there are no instances proved where unjust discriminations as to the quality of grain have been made, and that it is absurd to expect them to furnish to the public grain better than the official inspection requires. There seems little doubt, however, that opportunities do exist for the warehousemen who store grain for the public and who are also grain owners to get an advantage in the way suggested. This seems the more probable from the fact, brought out in the testimony of one or two witnesses who are especially familiar with grain inspection, that the official grading of grain is necessarily imperfect.

¹ Hill, 317, 318.

² Richards, 212-214.

³ S. H. Greeley, 231.

The bucket shops and the professional bear speculators are complained of as serious menaces to grain producers.¹

A committee of the Chicago Board of Trade reported in 1894 that the spirit of the Illinois warehouse law was against the practice of dealing in grain by warehousemen, and that grain was being held in Chicago too long for the good of the trade. The committee recommended that proprietors of public warehouses be prohibited from engaging in the grain business, and that certain improvements be made in the system of grain inspection.²

In nine cases brought by the Attorney-General of Illinois against the public warehousemen of Chicago the evidence appears to show that the warehousemen did not generally commence to deal in grain until about 1885, when the railroads made arrangements by which grain could easily be sold on track. The practice of selling by sample then became quite general. A system of through billing also arose during the eighties which operated against Chicago, and the railroads made rates discriminating against Chicago, thus diverting the grain to St. Louis and other points. One result was that much of the grain failed to go to the elevators in Chicago, the best grain being sold by sample, while "line-grade" grain went to the elevators. Cleaning houses and private warehouses were also established and diverted grain from the public warehouses, and the public warehousemen soon perceived that their business would cease to be profitable unless they dealt in grain. Their dealings in grain then grew so rapidly that they became the principal buyers and sellers in the Chicago market.

Judge Tuley, of Chicago, decided in the Chicago elevator cases that the warehouse law should not be so construed as to give the warehousemen the right to use their privileges to crush out competition, and that their dealing in grain was ultra vires and against public policy. This decision was affirmed by the Supreme Court of the State.

A bill was introduced into the Illinois legislature in 1897, soon after Judge Tuley's decision, giving the elevators the right to deal in grain, which is said to have been pushed by the elevator interest, and was strongly opposed by other grain dealers.³ It is said to be generally accepted by those who were present that the passage of the act was secured by the use of money.⁴

The Illinois law requiring grain to be weighed in hopper scales instead of track scales is said to be complied with only by part of the railroads.⁵ The charge of three-fourths of a cent a bushel for the transfer of grain from cars to vessels in Chicago is greater than the average freight rate by water during 1895 from Chicago to Buffalo.⁶

It is maintained that the present system of handling grain in Chicago, which consolidates the business on a given railroad into the hands of one buyer, is a detriment to the country through which the road runs, not only by depressing the price of grain, but also by displacing the former grain dealers in country towns by employees of the elevator companies.⁷

Western Elevating Association.—The tendency toward combination among the elevators is seen in the formation of the Western Elevating Association of Buffalo, the purpose of which is said to be to centralize the elevator business, to prevent cutting of rates, etc.⁸ While there has been an agreement among the Buffalo elevators for some time, it is charged that this has recently developed into a boycott of elevators outside of the association. Railroads agree to pay the association half a cent a bushel on all grain that passes through Buffalo and is shipped by rail. If they were to ship through an independent elevator they would be obliged

to pay charges both to the elevator and to the association, and charge the shipper half a cent more. The result is that the independent elevator gets practically no grain.¹ The association benefits the canal forwarders by giving free elevator service to grain shipped by the canal, but the elevators shipping by canal only have been driven out of business because the railroads own the majority of elevators.²

FOREIGN MARKETS.

Agricultural products amount to more than 60 per cent of the exports from the United States, cotton alone making nearly half the total.³ The primary and secondary products of agriculture, including flour, meat, etc., make up 80 or 90 per cent of all the exports.⁴ It is estimated that about one-fourth of the total agricultural production of the country is exported.

More than half of the agricultural exports go to the United Kingdom, and Europe as a whole takes about 80 per cent. In recent years, however, there has been a remarkable development of the Pacific trade.⁵ Most of the South American trade, however, is with Europe, and this is attributed to the fact that European nations have shipping facilities and have made a study of the export trade.⁶

There are said to be certain prejudices against American products in European countries, due to the fact that Americans have not always been careful to export their best goods.⁷ Thus complaints have been made that American grain sometimes reaches foreign ports in a moldy condition, the "tramp" steamers on which it is shipped not having proper facilities or sufficiently large crews to attend to proper ventilation. There have also been complaints about the grade of the grain, the rule for grading differing slightly at the different ports of shipment. Complaints have also been made of the flimsy baling of cotton.⁸ The importation of American live cattle was some time ago prohibited by Germany, France, Belgium, and the Netherlands on the ground that there was danger of introducing infectious diseases, though it is generally believed that the prohibition was really due to the agrarian movement in Germany, the object being to protect German products against competition. Belgium has removed the prohibition.⁹ A serious decline in the export trade in butter and cheese is attributed to the exportation of process butter and filled cheese.¹⁰

Foreign competition.—Several foreign countries have taken active measures to develop their export trade. Thus the Danish export butter is carefully inspected before shipment, and brings a high price in the English market. The Danes have also made a careful study of the British demand for bacon. Canada has developed a large export trade in cheese and butter by supervising the manufacture and indorsing the goods. It is said that some of the best American dairy products now find their way to Great Britain by way of Canada, branded as Canadian products.¹¹ The Australasian colonies have provided cold storage on trains to the ports of shipment, have sent agents to other countries to study methods, have furnished producers with careful instructions as to the products and style of packing desired by the foreign trade, and have followed the example of Denmark in offering prizes for the products best fulfilling the requirements.¹²

Exportation of grain.—Professor Davenport doubts the practicability and desirability of introducing American corn into Europe as a food product. He

says that in no country is it customary to use the same grain for human consumption that is fed to animals, unless it is raised in that country. He believes that we should at some time cease to export grain, but should export corn in the condensed form of meal.¹ It is also suggested that wheat should not be sent abroad except in the form of flour.²

The further development of Oriental markets is considered desirable, especially to increase the demand for wheat, which might perhaps be sent from the wheat belt to the Pacific for about what it costs to send it to the Atlantic seaboard. It is estimated that 40,000,000 bushels of wheat would be less than half a peck for each inhabitant of China, and it is pointed out that wheat flour has displaced rice wherever the two products have come into competition.³ On the other hand, it is suggested that if the Trans-Siberian Railroad should handle wheat more cheaply than American railroads are willing to handle it, it might become possible for Siberian farmers to send wheat to this country.⁴

ROAD IMPROVEMENT.

The poor character of American country roads is attributed to the early development of railroads in many parts of the country, which has made the need of country roads less imperative, and also to the scarcity of good road materials in many regions.⁵ The average cost of transportation on wagon roads has been estimated at about 25 cents per ton per mile, and on the best improved roads in this country between 10 and 15 cents, as compared with 8 cents on some European roads, one-half of 1 cent by railroad, and 1 mill by steamship on the Great Lakes. It is thought that four-fifths of the present cost could be saved, which would still leave the cost of transportation on roads ten times as great as on steam cars.⁶ The importance of road improvement is emphasized by several witnesses, who point out that where roads are good there are the most people and the greatest wealth.⁷ Good roads virtually bring the farmer nearer to market and save the necessity of disposing of products immediately or storing them in elevators, making it feasible to store grain in farm granaries, where the cost of insurance is less than in city elevators.⁸ (On the other hand, it is pointed out that the building of roads may in some cases entail more expense than the adjoining property is worth, and that, in view of the fact that in many agricultural sections the roads are in any case good during a large part of the year, the importance of road improvement may be overemphasized;⁹ but for farmers adjacent to large cities, especially dairymen who go to town every day, good roads are very important.¹⁰

The benefits of road improvement are illustrated by the experience of Mecklenberg County, N. C., where it is the policy to build a mile or more of macadam road at a time in various directions out from Charlotte, thus showing everyone coming to town the advantages of at least a little road improvement. Farming lands on macadamized roads within from 2 to 10 miles of town have increased from 50 to 100 per cent in value, suburban property having appreciated more than city property. Rural mail delivery has been made possible; larger loads of wood than formerly are hauled greater distances, with two horses instead of four, and hence may be sold at a lower price; products such as milk and butter, which formerly were not marketed, are now sent to town; and though there was opposition to the road tax at first, no complaints are now heard, and many counties in the State have adopted a system of road improvement.¹¹ There is also testimony from other

¹¹ Hutchinson, 1039-1041, 1044-1048.

localities—e. g. Alabama—to the effect that where good roads have been built lands have increased in value.¹

Road-improvement laws.—In many of the recent road-improvement laws provision is made for initiating improvements either by resolution of the county commissioners or by application of the abutting property owners. The New York law of 1898 is commended as, on the whole, the most satisfactory law. It provides that one-half the expense of road construction shall be paid by the State, 35 per cent by the county, and 15 per cent by the owners of the abutting land in proportion to benefits if the road is built on their petition, and otherwise by the town.²

In Illinois a measure similar to the New York law has been defeated by the farmers on the ground that under the present system of taxation the share paid by the State and county would come largely out of their pockets, as well as the share assessed directly upon their property.³ In the New Jersey law, which was the first of the State aid laws passed, one-third of the cost of construction is met by the State, one-third by the county, and one-third by the property owners benefited, and the roads are maintained at the expense of the counties.⁴

In Massachusetts, where the State undertakes road improvement, it bears the entire expense except the cost of reducing grades. The Highway Commission builds a mile of road here and there, partly as an incentive to the localities to improve their roads; and the intention is to bring these detached roads into communication, making a continuous highway through the State from east to west.⁵ In Ohio the cost of road improvement has usually been borne in the immediate locality, but roads are now being built in the counties containing large cities, and the cities are assessed for their share of the expense. Mr. Dodge proposes that the locality should contribute one-third, the State one-third, and the United States Government one-third, road improvement having become a matter of general concern through the increase in the distance traveled since the introduction of bicycles, automobiles, etc.⁶ Others who discuss the distribution of the cost agree that the entire expense should not fall upon the farming communities, but that State taxes at least may properly be used for road improvement;⁷ and Mr. Powers argues that the trend of population and wealth from country to city has created a moral obligation on the part of the cities toward the country, and that the cities should bear a part of the expense of rural roads and schools.⁸

It is estimated that 99 per cent of the entire road mileage of the country is still practically unimproved, and hence it is deemed advisable to diminish the necessary mileage and the cost per mile. The necessary mileage is likely to be reduced by the use of electric and other mechanical traction, and by the concentration of population in larger centers. It is estimated that by these means the average haul for wagons will be reduced to 2½ miles, and the maximum to about 5 miles.⁹ The cost of construction is diminished in some cases by utilizing convict labor,¹⁰ and road-building is considered one of the best forms of work for convicts, notwithstanding the care which must be taken to prevent their escape, because there is no competition with private enterprise.

Electric railways.—Attention is called to the importance of electric railways, both as an agency in relieving the isolation of farm life and for the transportation of farm products to market. The law of Ohio authorizing the use of electric railway tracks for the carriage of farm products is reported to have succeeded very well. The shipment of farm products on electric railways has been agitated in other localities.¹¹

ORGANIZATIONS AND COOPERATION AMONG FARMERS.

The organization of farmers is said to have been brought about as a result of the combinations in other lines of industry, which have forced farmers to combine for protection. Of late, however, the emphasis has been put less upon protection to the financial interests of the farmers and more upon education and improvement of social conditions in agricultural communities. The organizations have become somewhat more conservative than formerly as regards political action, and discuss a measure thoroughly before attempting to secure legislation.¹

While there is a general agreement that organizations of farmers are beneficial in various ways, one witness maintains that they tend to eliminate individuality and independence, and that they are apt to have too many rules and regulations.²

Farmers' organizations have sometimes succeeded in preventing attempted reductions in the prices of agricultural products and increases in the prices of goods bought by farmers.³ Some of them have succeeded in securing legislation in the interest of agriculture. Some have gone to pieces on the rock of politics, but the Grange has for many years avoided partisanship, and has become perhaps the most influential of the farmers' organizations.⁴

Agricultural cooperation.—There are in the United States in the neighborhood of 5,000 cooperative organizations maintained entirely or mainly by farmers, exclusive of irrigation companies. They are organized for a variety of purposes, such as cooperative buying and selling of goods, cooperative insurance, maintenance of small factories and shops, especially butter and cheese factories, mills and cotton gins, elevators, telephone lines, etc. These associations have often suffered from incompetent or even dishonest management and from lack of capital.⁵ The best instance of cooperation in the working up of agricultural products is perhaps afforded by the cooperative creameries.⁶ The Grange and, at least in North Carolina, the Farmers' Alliance have bought supplies cooperatively,⁷ but it is laid down as a general rule that this form of cooperation has been less successful than cooperative marketing of farm products; it has, in many cases at least, resulted in failure. It is suggested that farmers who attempt cooperation are not always true to their interests, and apparently do not trust each other enough to cooperate successfully.⁸

GOVERNMENTAL ACTION.

Department of Agriculture.—Secretary Wilson is quoted to the effect that the United States Government has interested itself in agriculture not only through the establishment of agricultural colleges in the States, but also in investigating the principles of agriculture and in collecting information about agriculture as a commercial enterprise.⁹ Dr. True compares the United States Department of Agriculture to a great experiment station.¹⁰ The work of several, but not all, of the bureaus and divisions of the Department is described in greater or less detail in the testimony. The Bureau of Animal Industry and the Division of Entomology not only have charge of practical work for preventing the spread of animal diseases and insect pests, to some extent in cooperation with the State authorities, but also conduct extensive scientific investigations having a practical bearing upon their work.¹¹ The Bureau of Forestry makes a study of the problems of reforestation, economical methods of lumbering, and protection against forest fires.¹² The Division of Chemistry has undertaken investigations of

various kinds which private individuals would not be likely to conduct, such as the quality of wheat needed for making macaroni, and the possibility of developing sugar-beet seeds.¹ The Office of Experiment Stations acts as a clearing house for information about agricultural education and research, and under its auspices independent investigations are made in certain lines, as in irrigation.² The Division of Statistics issues, among other reports, monthly statements concerning the condition of crops throughout the country, based upon data supplied by a large corps of voluntary correspondents and by salaried State agents, and supplemented by the reports of special traveling field agents. Printed cards summarizing this information are mailed to every postmaster in the United States monthly to be posted for the information of the public.³ The Department compiles statistics relating to exports of agricultural products, and has taken some steps towards developing the demand for American products abroad.⁴

State departments, bureaus, or boards of agriculture exist in most of the States, and are engaged in a great variety of activities.⁵ (See also Vol. XI, Part IV.)

Representation of farmers.—There is some complaint that agriculture is not as well represented in the National and State legislatures as it should be.⁶ On the other hand, it is pointed out that where farmers control the legislature, as in West Virginia, they divide on political lines.⁷

The tariff and the farmer.—Several witnesses agree that while farmers may be helped indirectly by the establishment of factories and the general prosperity due to the tariff, they receive little, if any, direct protection.⁸ Some go so far as to say that the tariff is injurious to the farmer on the whole, because it increases the prices of the articles he buys.⁹ Several specific cases are mentioned, however, in which farmers are thought to be benefited directly by the tariff. Thus, the farmers of New England are said to gain something from the protective tariff on agricultural products imported from Canada, especially hay and potatoes, and also from the duty on tobacco.¹⁰ The influence of the tobacco tariff is, of course, not confined to New England, but particular emphasis is laid upon the importance and the favorable opportunity of developing the cultivation of high-grade tobacco in the Connecticut Valley, and so keeping at home the money now expended for imported tobacco, especially from Sumatra, while at the same time diminishing the price to the consumer.¹¹ The tariff is also considered of great value to nurserymen and to producers of both sugar and rice,¹² and the duty on hides is said to help the cattle raisers materially.¹³ The duty on Mediterranean fruits very nearly offsets the higher fruit rate which California fruit growers have to pay in shipping their product to Eastern markets. Californians therefore oppose any reduction.¹⁴

Free wool.—During the free wool period many flocks of sheep were slaughtered, but since the reestablishment of the duty on wool there has been some increase in the number of sheep kept. There is some evidence to the effect that there is a tendency to overdo the business when the tariff is enforced. One result of free wool was that while the sheep were being slaughtered mutton was so cheap that the public acquired the taste for it, which it still retains. Under favorable conditions it is said to be possible to produce mutton as cheaply as beef, pound for pound, leaving the wool as so much clear gain. Sheep raisers favor the duty on wool, but are injured by agitation for changes in the tariff.¹⁵

Tariff on sugar.—Professor Kedzie believes that the sugar tariff should continue for the present, because it would be disastrous to the sugar industry of this

country to cut the price of sugar down below the cost of production here. He believes that ultimately, however, when the industry is thoroughly established, the tariff will be unnecessary.¹

Commercial effects of expansion.—Fears are expressed that free trade with Porto Rico and the Philippines will result in a new and severe competition, especially in tobacco and sugar. On the other hand, it is suggested that the annexation of territory will enlarge the market for American goods, and benefit farmers together with the rest of the country.²

STATE AND LOCAL TAXATION.

A large number of witnesses, representing nearly every section of the country, discuss the relative burden of State and local taxation upon agricultural and other interests, and nearly all agree that farmers are overtaxed as compared with residents of cities, mainly because all farm property is tangible and visible to the assessor, while many of the forms of personal property owned in cities are easily concealed.³ Only four witnesses express the opinion that agricultural and other property in their respective States are equally taxed, though one other thinks that farm land in North Dakota is taxed lower than other property.⁴ The farmer is accused of being chiefly to blame for the personal-property tax, however, always demanding it on the mistaken hypothesis that business men would escape if personal property were not taxed.⁵

Farmers and others whose land is mortgaged suffer an additional disadvantage because of the taxation both of mortgages and of the mortgaged real estate. This results in the farmer paying the tax on the whole of the property, and also an increased rate of interest to his creditor.⁶

Proposed reforms.—Several devices are proposed for improving the administration of the existing general-property tax.⁷ For example, it is urged that assessors be appointed where they are now elected,⁸ and that taxes be equalized between localities on the basis of the amount of the taxes locally raised instead of the assessment.⁹ On the other hand, fundamental objections are urged against the general-property tax, and it is held that the systems of taxation in most of the States need complete remodeling, conditions having changed radically since they were adopted.¹⁰ Several witnesses advocate State income, inheritance, and corporation taxes.¹¹ Two witnesses favor a graduated income tax.¹² Others, while not advocating an income tax as such, favor the taxation of property according to its income-producing capacity rather than its selling value.¹³

Taxation of land values.—Three witnesses advocate the adoption of the single tax on land values.¹⁴ The editor of the *Farmers' Voice* speaks for it with particular reference to the interests of the farmers. Mr. Ralston makes a more general argu-

ment in favor of it. Several legislative attempts to introduce it in the United States are spoken of, including a constitutional amendment pending in Colorado. Two actual trials of it in local taxation are mentioned, both of which, however, were ended by the courts on the ground that they were unconstitutional. The approach to the system in New Zealand is also referred to.

PROPOSED NATIONAL LEGISLATION.

Education.—More generous aid to agricultural colleges and experiment stations is considered desirable,¹ though one witness proposes that the proceeds of the land-grant funds be used in the South for the support of farmer's institutes.² It is suggested that a national appropriation in aid of the common-school systems of the Southern States would be of great benefit.³ (See also Vol. XV.)

Investigation of conditions in the South.—There is a demand in the South for an official Governmental inquiry into the economic and general condition of the negroes and of the white tenant farmers, under expert supervision; and it is suggested that the expert preparing the schedule for the inquiry should himself take testimony on the ground. It is urged that there is great need for the collection of statistics showing the conditions existing in that part of the country. It is especially urged that the conditions of agricultural labor in the Black Belt and other typical sections of the cotton region be investigated by the Industrial Commission or otherwise.⁴

Fertilizers.—Mr. Whitney mentions the desirability of national legislation governing interstate commerce in fertilizers.⁵

Irrigation.—Mr. Mead expresses the opinion that reservoirs located in the channels of streams, and especially on the headwaters of streams in the mountains, should be built as public works. He also calls attention to the fact that a number of bills have been introduced in Congress to give to the arid States the proceeds of the sales of public lands within their borders as a fund with which to construct irrigation works, and suggests that the revenues derived from the public domain could be largely increased by collecting rent from the public grazing lands, over which flocks and herds now roam gratis and without restriction, to the great damage of the grasses, if not also to the injury of Eastern farmers by unfair competition.⁶ Mr. Greeley, of South Dakota, also urges governmental action to supplement the natural water supply of the West by the creation of artificial lakes and streams, and suggests that large sums now expended in river improvement might well be diverted to this use.⁷ Among Eastern farmers there is some opposition to Governmental aid to irrigation enterprises, chiefly on the grounds that it would constitute an undue assistance to their Western competitors and that the additional land is not yet needed for the production of crops.⁸

Seepage.—Mr. Whitney points out the desirability of either State or national legislation to stop the injury done in the West by seepage waters. He says that canal companies should either be compelled to protect their canals against percolation or pay damages to those injured by the accumulation of water and alkali on their land as a result of the seepage.⁹

Protection of grazing lands.—Quite apart from the suggested desirability of securing a revenue from the grazing lands of the public domain, it is considered necessary for the Government to exercise some control over them in order to prevent the injury caused by too close grazing.¹⁰ A system of leases is proposed, in connection with such a disposition of irrigable lands as would enable each irrigator to lease some contiguous pasture land, the leased land, however, to remain

¹⁰ Whitney, 861; Mead, 1063, 1064.

subject to entry under the existing land laws, in order that there should be no obstacle to the permanent settlement of areas suitable for cultivation.

Diversification of crops.—Mr. Powers maintains that the State ought to take the lead in ascertaining what new agricultural industries should be established in each locality, and that the Nation should ascertain the crops and methods suited to the older sections of the country under the changed conditions now prevailing.¹

Forestry.—There is a strong desire for legislation to preserve the evergreen forests of the Northwest, and it is proposed that great parks of these trees be maintained, especially at the heads of great rivers and on poor nonagricultural lands. Mr. M. F. Greeley declares that the greatest thing Congress can do for the nation is to set aside such parks, and that the expenditure will more than pay for itself in doing away with the necessity of building dikes to protect the lower valleys against floods.² The beneficent influence of forests in preventing both floods and droughts is also pointed out by Mr. Hamilton and Mr. Naftzger; and the latter, besides urging the preservation especially of the forests on the Pacific slope, proposes the transfer of the forest reservations from the Interior to the Agricultural Department, in order to secure a more efficient protection against fire.³

River improvements.—Mr. Budge suggests that the channel of the Missouri River be dredged and provided with pile bars to narrow the stream and extend navigation, and to prevent destructive floods. He also suggests a series of bars and locks on the Red and Red Lake rivers.⁴

Insect pests.—There is a demand from various sources for a national quarantine law against insect pests, such as that provided for in the bill (S. 5615, Fifty-sixth Congress, second session), which has already been favorably reported to the House of Representatives.⁵ While there was at first some opposition to this measure among the nurserymen, a memorial strongly urging its passage has been submitted to Congress by a committee of the American Association of Nurserymen, and the opposition seems to have subsided. At any rate, the need of more uniform legislation against insect pests is generally recognized, and Dr. Howard proposes a second national convention to agree upon details. There is a demand from Massachusetts for continuation by the National Government of the work for the extermination of the gipsy moth, which has been suspended by the State government.⁶ Dr. Howard suggests as a rule for dividing such work between the State and national governments that the State affected ought to do the work except where the insect may be reasonably expected to spread over a number of States.⁷

Diseases of animals.—There is a general demand for national legislation to prevent the spread of disease among animals.⁸ It is argued that the Bureau of Animal Industry, having done such excellent work in the eradication of pleuropneumonia, could do equally well with tuberculosis and glanders,⁹ and that local laws are never effective against such a disease as sheep scab.¹⁰ The desirability of uniform legislation is conceded even when Federal legislation is not advocated.¹¹

Dr. Salmon proposes that the Secretary of Agriculture be given authority to require the cleaning and disinfection of stock cars and stock yards and the proper disposition of diseased meat; also to make regulations prohibiting the shipment of uninspected meat from State to State or to foreign countries, so far as necessary to guard against the use of diseased products. He also suggests a more comprehensive penalty clause for shipping condemned meat, in order to prevent certain ingenious evasions of the law, and adds that the penalty for shipping diseased animals from one State to another should be made to apply to railroads which are in the hands of receivers, as well as to other railroads.¹²

LXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Food adulteration.—There is a very general demand for national pure food legislation, in view of the difficulties of State regulation and the need of uniformity. Several witnesses propose that the enforcement of the proposed law should be entrusted to the Department of Agriculture. Specific proposals as to the nature of the proposed legislation are (1) that all food products should be required to be labeled so as to show their true constituents; (2) that food products brought into a State should immediately become subject to the State law, even if in original packages, and (3) that food products entering into interstate commerce should not be permitted to be falsely branded as to the State in which they are made. Dr. Gehrman, besides emphasizing the importance of uniform legislation, lays down the general principles that pure-food laws should be very explicit; that the inspectors should be interested in their work and sufficiently numerous to secure an efficient enforcement of the law; that the chief officer in charge of the administration of the law should be a man of executive ability, having also scientific qualifications; and that every case of adulteration should be fully tried, political and personal considerations being strictly excluded. He also suggests publishing the names of violators of the law as a most effective punishment, and adds that the public should be educated regarding the requirements of the law.¹

Oleomargarine.—Many witnesses especially urge national legislation to restrict or regulate the sale of oleomargarine, either by requiring it to be distinguished from butter by coloring or labeling, or by a decided increase of the tax, e. g. to 10 cents a pound. Mr. Hamilton points out that at present the oleomargarine business is so profitable that the temptation to fraudulent substitution is very great, and he advocates an increase of the tax to 10 cents so that the manufacturers could not undersell the dairymen.²

Speculation.—Several witnesses favor national legislation to prevent local dealing in options and futures, especially in bucket shops.³

Inspection and grading of grain—Regulation of elevators.—In order to prevent manipulation of grades by warehousemen and other dealers in grain it is proposed that a national grade be established as a basis, all grain grading above or below that grade to be sold at a premium or discount. It is believed that this would result in saving to the farmer some part of the profits which now go to middlemen.⁴ Other proposals are that the terminal elevators should be placed under the control of the General Government, and that inspectors should be appointed at public warehouses to prevent the warehousemen from trafficking in or mixing grain or from keeping the better qualities of their customers' grain and delivering the poorest quality.⁵

Railroad discriminations, etc. (See also Vols. IV and IX.)—One of the measures proposed in connection with the railroads is that all discriminations, special rates, and rebates should be prohibited.⁶ One witness advocates the legalization of pooling under such supervision as would give the public the benefit of whatever advantage the railroads would derive from it,⁷ but this proposal does not appear to be popular, among either farmers or grain merchants.⁸

Interstate Commerce Commission.—There seems to be a general feeling that the powers of the Interstate Commerce Commission should be increased.⁹ It is pro-

posed, for example, that the commission be given the authority to enforce its rules and regulations;¹ that it should have power to determine what are reasonable rates, and to classify rates;² and that it should have supervisory power to control various matters connected with the interstate commerce, including the weighing, storage, inspection, and transfer of grain.³ It is also suggested that one member of the commission should be an agriculturist, while one should represent manufactures and one commercial interests.⁴

Government ownership of railroads.—The necessity of Government control over railroads leads three witnesses to suggest Government ownership, but it is pointed out that this should not be undertaken without a satisfactory civil-service system.⁵

Regulation of corporations and trusts.—In view of the ill success of State legislation to regulate industrial combinations, it is proposed that Federal legislation be enacted for the purpose, at least where interstate business is concerned.⁶ It is suggested that protective duties be removed in the case of industries which are in the hands of great combinations.⁷

Cooperation.—Mr. Holmes suggests that incorporated cooperative companies should be subject to the supervision of State officers, and that those engaged in interstate commerce might preferably be provided for by national legislation.⁸

Department of Agriculture.—It is suggested that the annual appropriation for the Department of Agriculture should be increased to at least \$10,000,000, to enable it to keep pace with the importance of the industry. A specific extension of the Department's work is asked for in the collection of statistics relating to the cost of raising important agricultural products.⁹ It is also suggested that the Department continue its experiments in the growth of high-grade sugar-beet seed, as it is considered desirable and necessary that the seed should be grown in this country.¹⁰ Mr. Hammond urges the establishment of a division of mechanics to give information of mechanical improvements, in order that the mechanical progress of agriculture may keep pace with that of other occupations.¹¹

Banking.—Southern planters urge that the national banks be permitted to loan money on real estate security, in order that loans may be negotiated more readily and at reasonable rates of interest, and that the 10 per cent tax on the circulation of State banks be removed.¹²

Postal savings banks.—Several witnesses recommend the establishment of postal savings banks. The National Grange is said to be in favor of such banks.¹³

Direct election of Senators.—The National Grange also favors the direct election of Senators.¹⁴

Tariff.—There is some demand for increased tariff protection to agricultural interests. It is stated that between three and four hundred million dollars' worth of agricultural products are imported which should be produced in this country, and that the encouragement of their production at home would help to diversify agriculture. In particular, higher duties on wool and hides are called for;¹⁵ and a reimposition of the duty on foreign-grown hemp is especially urged as a means of needed encouragement to the hemp-growing industry of Kentucky.¹⁶ Mr. Wedderburn, though not in favor of protective duties in general, suggests that the cultivation of long-staple cotton might well be encouraged by a tax on imports.¹⁷ California interests are opposed to any reduction of the tariff, especially on fruits,

¹⁷ Pages 620, 627.

even by means of reciprocity treaties;¹ and Mr. Saylor favors a continuance of the duty on sugar, even from Porto Rico.²

Extension of foreign markets.—Comparatively little effort has been made to develop the agricultural export trade of the United States, and attention is called to the desirability of Government action for that purpose, and also to the need of a careful study of the tastes and requirements of foreign countries. It is considered especially desirable to secure new customers for the cotton crop, two-thirds of which is exported.³

It is generally agreed that a system of Government inspection of export products should be provided for, especially in the case of dairy products. Mr. Hitchcock proposes a system of optional inspection for grain, believing that a Government certificate would enhance the value of the grain in Europe.⁴ Other proposals for extending the foreign trade are a continuation of the experimental shipments of butter already inaugurated by the Department of Agriculture;⁵ an improvement of the consular service;⁶ the employment of traveling special agents and agricultural attachés to American embassies in foreign countries;⁷ exhibits at expositions, permanent exhibits in foreign countries, and advertisements in foreign newspapers and magazines;⁸ the appointment of an export commission;⁹ the encouragement of cold-storage facilities at the ports, and of improved cold-storage transportation facilities;¹⁰ the opening of an Isthmian canal, which is especially desired by the people of the Pacific coast and the South,¹¹ but is said to be opposed by some Northern farmers;¹² the development of American shipping by means of subsidies,¹³ and export bounties on staple agricultural products.¹⁴

Export bounties.—Mr. Wedderburn argues that an export bounty on staple agricultural export products, by making it profitable to raise and export grain, cotton, and tobacco, would stop the Southern and Western competition with the Eastern truck farmer, and so benefit New England as well as the parts of the country producing the staples.¹⁵ Mr. Powers opposes the export bounty; he says the result would be the same as in the case of the German sugar bounty, which has made sugar so cheap in England that farmers feed raw German sugar to their hogs, at the expense of the German taxpayer, while the bounty has raised the price of sugar to the German consumer and thus lessened the amount consumed. Mr. Powers maintains that if the bounty were removed the increased consumption in Germany would in time create a market for as much sugar as the export bounty has.¹⁶

Rural mail delivery.—All the witnesses who discuss this subject are emphatically in favor of rural mail delivery as a great convenience and benefit to farmers. It is argued that those who live in the country are as much entitled to free mail delivery as those who live in cities, and that it would be a great economy to do away with the necessity of daily trips to town. It is also believed that the use of the mails would increase.¹⁷

Road improvement.—It is proposed that the United States Government bear some part, e. g. one-third, of the expense of road improvements.¹⁸

INDEX OF REVIEW AND DIGEST	CCCLXXX

TOPICAL DIGEST OF EVIDENCE.

I. PROGRESS OF AGRICULTURE DURING THE NINETEENTH CENTURY.

A. Numerical importance of the agricultural industries.—1. **Number of farmers.**—Mr. POWERS, of the Census Office, says that from 1850 to 1890 the population of the United States engaged in agriculture increased from 13,500,000 to 27,000,000. The farm owners, who in 1850 were a little more than 50 per cent of the farm families, increased to a little more than 60 per cent in 1890, laborers and tenants decreasing to about 40 per cent. The slaves represented in 1850 about 19 per cent of the farm families, and wage laborers about 16 per cent. Although the number of wage laborers was increased by the emancipation of the slaves, it has relatively decreased since that time, while tenancy has increased in a very marked degree. (170.)

Mr. HOLMES, of the United States Department of Agriculture, says the agricultural element is the largest one in our population. In 1890 out of 22,750,000 persons employed in all gainful occupations, 8,500,000 were employed in agricultural occupations of all sorts. Of these 3,000,000 were agricultural laborers working for wages, and 5,500,000 were farmers of the proprietor class, including owners and tenants. The farming element constitutes one-third of the population, and while the capital employed in agriculture is small compared with that invested in manufacturing and mechanical industries, it is numbers of people rather than dollars of wealth that are entitled to primary consideration. (152, 157.)

Mr. STOCKWELL, secretary of the Massachusetts State Board of Agriculture, states the number employed in agriculture in Massachusetts as follows: 1875, 74,500; 1885, 77,661; 1895, exclusive of agricultural laborers, 37,556. Mr. Stockwell apparently believes that the percentage of increase of the previous decade held good from 1885 to 1895. (884.)

2. **Number and value of farms.**—Mr. A. J. WEDDERBURN, master of the Virginia State Grange, quotes the report of Hon. William H. Hatch as chairman of the House Committee on Agriculture (Report No. 1999, Fifty-third Congress, second session, March 2, 1895) as showing that the number of farms in the United States increased between 1880 and 1890 from 4,008,907 to 4,564,641, or 16.25 per cent, while the number of farms in New York, Pennsylvania, and New England decreased 5.4 per cent, and their acreage decreased 7.70 per cent. In 1860 the farmers' wealth was nearly one-half the wealth of the entire country, but in 1890 it had decreased to one-fourth, notwithstanding the vast increase in acreage, capital, and production. (628.)

Mr. STOCKWELL also calls attention to a decline in farm values. In 1850 the farmers owned one-half the wealth of the country; in 1890, only one-fourth. (891.)

Mr. POWERS says the value of farms at the Eleventh Census was a little over \$13,000,000,000, that of live stock and farming implements a little less than \$3,000,000,000; making a total of about \$16,000,000,000. (184.)

Mr. STOCKWELL shows by a comparison of the census figures of 1880 and 1890 a considerable diminution in the number, acreage, and valuation of Massachusetts farms. The total capital employed in agricultural pursuits in Massachusetts in 1895 was \$219,557,214. (887, 888.)

Mr. POOLE, Commissioner of Agriculture of Alabama, says there has been a small but steady increase for years in the amount of land cultivated in that State. (924.)

Dr. CROWELL explains the small increase in the value of farming property by the

fact that the rewards of capital and labor are much lower in agriculture than in other lines of activity, and that inequality tends to throw capital out of agriculture. (339.)

3. Productivity of agriculture.—Professor BAILEY, of the College of Agriculture of Cornell University, illustrates the increase of agricultural production by certain statements relating to average crops toward the close of the eighteenth century. It was said in 1791 by an observer living within 6 miles of Philadelphia that 8 bushels of wheat to the acre was a fair allowance for the better kind of farms in those parts; that some did not yield 6, and that eight out of ten did not come up to 8. Mr. Bailey says that the yield of wheat in Pennsylvania and the adjoining regions now averages at least twice these figures, and the best farms do much better. The same observer said in 1791 that dairy cows averaged 2 pounds of butter a week, or 104 pounds a year. An ordinary farm dairy to-day in that region, says Mr. Bailey, should average 250 pounds of butter to the cow, and the best herds will produce more. Mr. Bailey also quotes an extended estimate of the average production of a good farm in Bucks County in 1791. His conclusion is that the average productivity of a farm is four to six times greater to-day than it was in the same section 100 years ago. (1004-1006.)

Among the reasons for increased productivity of farm land Mr. Bailey enumerates the use of better tools, the use of commercial fertilizers, and the more general appreciation of the value of tillage and of the rotation of crops. The better markets and the greater competition stimulate activity and energy. A greater range of products is in demand. Diseases and insects are under better control. Elsewhere, however, Mr. Bailey says that insects and diseases have grown more numerous and more serious because of the introduction of new pests by commerce and because of the greater variety of crops, the greater extent of crops of one kind, etc. He adds, however, in this connection, that in many cases the farmer has a recourse for the destruction of pests, and that his resources in such directions are greater to-day than they were 100 years ago. (1006, 1013.)

According to the census returns the aggregate value of farm products remained nearly stationary from 1870 to 1890, while the value of manufactures nearly doubled between 1880 and 1890. Mr. HAMMOND, of South Carolina, criticises the census figures, however, as being subject to important corrections. The census of 1890 reported as manufactures many small industries which had not previously been included under that head. The census returns make no allowance for the value of raw material consumed, which is estimated in the census returns as considerably more than half the gross value of manufactured products. Moreover, many manufactured products are used as material for other manufactures, and the values of them are counted again and again. (835, 836.)

Mr. HOLMES thinks it very doubtful whether the product per acre has increased on the whole. The statistics of agriculture do not indicate any distinct movement toward intensive agriculture, though it is well known that such a movement is taking place in special directions. (156.)

Mr. WEDDERBURN says that between 1880 and 1894 there was an increase in production and in the yield per acre, but a loss of \$248,299,825 in the money value of the product. (628.)

Mr. BRIGHAM, Assistant Secretary of Agriculture, believes that the farmers made a larger profit on a given investment 40 years ago than to-day. The valuation of land and of cattle was lower, so that a man could get more from the same investment. Nevertheless, a dollar will now buy a good deal more of most kinds of goods than formerly, agricultural implements especially being cheaper and better. (13.)

Mr. NALL, Commissioner of Agriculture of Kentucky, says that the agricultural products of to-day are more valuable in the aggregate than 50 years ago, because there is a larger capital employed; but he doubts whether, acre for acre, more wealth is produced now than before. (809.)

Mr. STOCKWELL declares that the United States as a farming nation is equaled by none in the amount of its agricultural productions. "The grain is finer, the fruit more luscious, the flower more beautiful than ever before." The farmer each year adds to the wealth of the country far more than all other industries combined. The total value of agricultural products for 1898 was \$4,000,000,000, and the relative value as shown by the exports has averaged nearly 80 per cent for the last 50 years. (891.)

4. Agriculture the fundamental industry.—Mr. STOCKWELL says the prosperity of agriculture is the foundation of National wealth, and is a matter for Congress to consider very carefully. (892.)

B. Prevalence and limitations of agricultural prosperity.—*In the East generally.*—Dr. CROWELL says the localities in the East with which he is most familiar have rapidly advanced in the last decade, both in the condition of agricultural labor, in the earnings of agriculture, and in the ability of farmers to send their children to higher institutions of learning. (337.)

Mr. NORRIS, master of the New York State Grange, thinks that farmers in the older sections of the country are in a worse condition on the average than they were 30 years ago. He adds that where the farmers of the Eastern States have depended entirely upon growing cereals, they have run behind and had to mortgage their farms. (326, 327.)

New England.—Mr. BACHELDER says the farmers of New England have suffered greatly from western competition, but are to-day more prosperous than ever before. Owing especially to the efforts of the Grange, which is exceedingly active in New Hampshire, the social conditions and opportunities for enjoyment among the farming classes have been greatly improved. (40, 41.)

Mr. STOCKWELL says that the Massachusetts farmer, after being in a bad condition for 4 or 5 years, has become prosperous. There is a marked improvement; he has turned his attention from the old lines to the new, and prices and conditions are better.

Mr. Stockwell considers the prosperity of Massachusetts farmers in 1899 and 1900, in spite of the drought, a wonderful illustration of what can be done by intelligent culture and of the strength of the Massachusetts soils. (893, 901.)

Mr. Stockwell says the progress of agriculture, the influence of the State board and its institutes, the work of the Grange, and the increase in all other lines are reflected in better conditions in the farmers' homes all over Massachusetts and in a higher plane of living. The laborers on the farms enjoy better conditions of life than formerly. The surroundings of the home are more neat and more beautiful than formerly. (884.)

New York.—Mr. POWERS questions whether the New York farmer is doing as well as 20 years ago. He turns off as much money, but is spending more in connection with his farm. New York farm owners and tenants live better, however, than 15 years ago. (178.)

Mr. STOCKWELL says the New York Society for Improving the Condition of the Poor recently made an exhaustive inquiry into the agricultural depression in New York State. Mr. Kjelgaard, an intelligent Pennsylvania farmer, was employed to travel through the agricultural districts, and Mr. George T. Powell investigated the subject by correspondence. Mr. Stockwell quotes from the report made to the society, showing that farming land had depreciated; that 30 per cent of the farmers were anxious to leave their homes, that 86 per cent reported that their children could not be influenced to remain on the farms, that tenant farming was on the increase, that 35 per cent of the New York farmers were losing money, 50 per cent were dangerously near doing so, and 14 per cent making a profit, while 20 per cent did not know whether they were or not. (888, 892.)

Professor BAILEY quotes 20 replies from representative New York farmers to questions as to the existence and the causes of agricultural decline. Only 6 out of the 20 seem to Mr. Bailey to indicate that there is a general depression in agriculture, and even in these cases the decline does not seem to make the respondents hopeless. Several of the correspondents point out that the question may be differently answered according to one's understanding of it. Some of them regard the decline of the value of farm land as an evidence of agricultural depression. Others, looking at the matter from the standpoint of the worker and possible buyer of land, take a different view. One says: "I think that there has never been a more favorable time to buy a farm and pay for it from the soil than now." Others point out that while land values have declined, farm products bring prices that are profitable, if intelligence is applied to raising them, and that farm wages are higher than they were years ago. (1006-1010.)

New Jersey.—Mr. COLES, a farmer and dairyman, of Woodstown, N. J., says the condition of agriculture in his section is not very prosperous. Prices are generally lower than formerly, though perhaps agricultural products are no more affected than the products of other industries. There is some feeling among New Jersey farmers that they suffer from the low freight rates for long hauls from the West. Real estate has been reduced in value. The profits of many farmers are reduced by the interest on land bought at higher prices. (122, 123.)

Mr. Coles adds, however, that the home comforts and enjoyments of the New Jersey farm are greater than formerly. Most of the farmers in his section have fairly good homes, horses, and carriages, and live about as well as other people. Where there is any talent for music, they try to have a musical instrument in the house; generally an organ, but often a piano. The children are better educated than formerly; some go away to school or college. (125, 129.)

Mr. KETCHUM, of Pennington, N. J., says that the farms in that vicinity are generally devoted to mixed agriculture—potato farming and dairying. South of Trenton there is some truck farming. He thinks the condition of agriculture and the profits on the capital employed compare favorably with the period preceding the civil

LXXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

war, but not with the period immediately following it. Farms in that section are all occupied, and new lands have been cleared and wet lands reclaimed by underdrainage. (132.)

Ohio.—Mr. MILLER, secretary of the Ohio State Board of Agriculture, thinks the Ohio farmer is in a much better condition now than he was before the war. He complains because he feels that he is not as prosperous as he was at a given period after the war, when the increased demand for agricultural products greatly affected their prices. Mr. Miller knows of no abandoned farms in Ohio. (614.)

Illinois.—Mr. GEORGE, of Chicago, says the condition of agriculture in Illinois is vastly improved, as compared with 40 years ago, though it might be still better. The farmers live in more comfort, and have much better educational and social privileges. Mr. George remembers the time, from 1840 to 1844, when farmers could not find a market for corn in Illinois, even at 10 cents a bushel in exchange for merchandise, and when pork could not be sold at any price. (223, 224.)

Minnesota.—Mr. HANLEY says that all the farmers within 30 miles of St. Paul are wealthy; "probably none of them is worth less than \$20,000." They have the benefit of the terminal market at St. Paul. (274.)

Mr. MORAN, of Minnesota, thinks the tendency is for the farmers to live a little better than 25 or 30 years ago, but that they still can not afford to live as well as they ought to. (711.)

The Northwest.—Mr. PRATT, of Aberdeen, S. Dak., thinks the farmers of the Northwest are doing better and feeling better than formerly. They farm better and are diversifying and raising stock. (727.)

Mr. JUMPER, also of Aberdeen, says the farmers of South Dakota have learned by experience and understand the soil a good deal better than formerly. The condition of the farmer has advanced every year for 4, 5, or 6 years; it is now very good and is still advancing. (734.)

Mr. POWERS says that on the frontier of to-day, in the semiarid regions of the West, a greater percentage of those who try to make homes succeed than did so in central New York at the beginning of the century. In the early settlement of central New York a great deal of land was taken up under contract, and not one-fourth of the men who thus took land ever perfected the title. The chances of a man paying off a debt on a western farm are at least ten times what they were in central New York at the beginning of the century. (171.)

Maryland.—Mr. AGER, master of the Maryland State Grange, says there was a great deal more land under cultivation in Maryland 40 years ago than at the present time. A great deal has grown up in timber, and along the railroads many farms have been subdivided into small town sites. The average condition of agriculture is not as good as it was 40 years ago, though in every locality there are industrious farmers who are making money. (104, 109.)

Virginia.—Mr. WEDDERBURN says there is a decided improvement among the farmers of northern Virginia, but as a rule the farmers have not made much money, and have had to be very economical. The cost of production and of everything used in production is too high for profit. (623, 624.)

West Virginia.—Mr. CLOHAN says there has been a steady improvement in the condition of the farmers of West Virginia, and is very hopeful for the future. (603.)

North Carolina.—Mr. GRAHAM, member of the North Carolina Board of Agriculture and president of the State Farmers' Alliance, says there were some exceptionally fine farmers in North Carolina before the war, but he thinks the farmers as a class have improved in their methods since that time. They are more intelligent and live better than 30, 40, or 50 years ago. Agriculture has not been remunerative in North Carolina for several years past, however. (433, 434.)

South Carolina.—Mr. YOUNG, a farmer and merchant of Fairfax, S. C., testifies that in his section agriculture is in a deplorable condition; in spite of the fertility of the soil, the propitiousness of the seasons, the industry of the people, and abundant harvests, there is hardship and distress, which must be due to an artificial cause. Small landholders are being forced to give up their land, and it will be only a question of time until the large landholders must do the same. The proceeds of the crops will not pay the expense of production. Scarcely any crop is profitable. The tendency of prices is downward, though there are temporary reactions in certain lines. Mr. Young says he can not get \$5 for what he could sell 20 years ago for \$20. He believes that in the matter of prices history repeats itself, and refers to the decline in the twenties and forties, the rise in the fifties, and the decline since 1872. Mr. Young says he made money steadily as a cotton planter until 1890. (117, 118.)

Georgia.—Mr. STEVENS, Commissioner of Agriculture of Georgia, testifies that the progress of Georgia in all lines of industry has been very marked during the last decade, and especially so in agriculture in the last two years. Mr. Stevens regards

the increase of urban population as an evidence of gratifying growth in the diversity of industrial pursuits, arguing greatly increased prosperity. There is a larger percentage of attractive homes among the agricultural population than at any previous time.

The present condition of the agriculturists of Georgia is much better in every way than for many years past. The country banks hold a much smaller number of farmers' notes, and for smaller amounts, but have much larger deposits from the farmers than ever before. (905, 906, 915.)

Mr. BROWN, president of the Georgia State Agricultural Society, testifies that the landholders and the laborers of his State alike have lost ground materially during the past few years. The small farmer, who works his own land and does not hire labor, is more prosperous than the large farmer and landowner, although he has few luxuries and lives mostly on what he can himself raise. (60.)

Mr. REDDING, director of the Georgia Agricultural Experiment Station, thinks the Georgia farmer is a little harder up than he was before the war. He has known of a good many cases where men have been sold out to pay their creditors. (443, 445.)

Mr. BARRETT, of Augusta, Ga., testifies that Georgia is not prosperous. The tax returns have decreased within the last few years. (51.)

Alabama.—Mr. POOLE, commissioner of agriculture of Alabama, says the condition of agriculture in Alabama is better by 50 per cent than it was 15 or 20 years ago. Since about 1890 there has been a steady increase of prosperity every year. (924, 925.)

Southern agriculture before the war.—Mr. NUNNALLY, a cotton planter of Georgia, testifies that even in the old days of luxury and ease in the South a man who did not inherit anything, but was obliged to face poverty from the beginning, usually remained poor. The implements of husbandry were few and primitive. The practice was to work out the soil and move on to more productive fields. That day of devastation is over. The land has been reclaimed, and produces far richer crops than in its early freshness. (454.)

Agricultural depression in the South.—Mr. DILLINGHAM says the whole agricultural industry of the South is depressed. The small white farmers are in the same condition as the colored farmers. He believes that the Southern farmers must fertilize the soil and raise their food. (168.)

Recent Southern prosperity.—Dr. STUBBS, director of the Louisiana experiment stations, says all the Southern States are in first-class condition at present. Money is abundant; farmers are cheerful, and are improving their farms and diversifying their agriculture. Among the whites there is less moving about, less disposition to sell, more endeavor to improve and embellish the home than Dr. Stubbs has ever seen before. There are fewer mortgages, less dissatisfaction, more home comforts, more education, more live stock, more fertilizers used, and better attention paid to farming. In the nature of things, this condition is not permanent, because if the bottom should drop out of either of the staple crops—cotton, sugar, or rice—the South would suffer. These interests are prosperous because prices are fairly good. Six or 8 years ago the cotton planters found it difficult to make both ends meet, selling the crop at 4 cents a pound and having to buy things at higher prices than now, and they passed through very desperate straits. Rice and sugar are liable to these fluctuations, as well as cotton. (782.)

Mr. STEVENS, Commissioner of Agriculture of Georgia, says the condition of the farmers of Georgia is not what it ought to be, but has improved of late. The short cotton crop of 1899, and the fact that Southern mills used more cotton than ever before, combined to raise the price of cotton; the South fixed the price for the first time. In addition to that, the farmers of to-day are raising their own supplies of food, not only of vegetables, but of meats, and harvested more wheat in 1900 than in any other 3 years since the civil war. Mr. Stevens believes that Georgia has unsurpassed agricultural possibilities. (916, 917.)

Mr. BALCH, of Little Rock, Ark., testifies that the cotton farmers have prospered more for 2 or 3 years preceding the date of his testimony (March, 1900) than for many years before, and that the South is in better condition than ever before. Large amounts of capital are being invested in mills, giving employment to labor between laying-by time and cotton-picking time, and between cotton picking-time and planting time. Mr. Balch attributes much of the improved condition of the planters to success in inducing the colored people to buy less in the way of supplies than formerly. (496, 497.)

Mr. HILL, of Memphis, thinks the condition of the farmers and planters in that vicinity has improved somewhat in the past few years, but is not as good as for a short time after the war, when labor was more to be relied upon and the price of cotton was high. (503.)

LXXXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. NORFLEET, a cotton factor of Memphis, testifies that there was less demand for loans in the spring of 1900 than for 15 years before, on account of the higher prices of cotton. (488.)

Mr. MOSELEY, a cotton dealer of Memphis, testifies that the year 1899-1900 was a remarkable year, and that the country is in better condition (March, 1900) than for a number of years. A great many mortgages have been paid off. (515.)

Mr. KYLE, of Mississippi, also considers the condition of the cotton planters better (March, 1900) than for several years. More people have money to loan, prices for cotton and other products having been better. Cattle and sheep have realized good prices. (470.)

C. Causes of agricultural depression.—Professor BAILEY thus summarizes the causes generally assigned by his farmer correspondents for the so-called agricultural depression:

"First, economic conditions, comprising depreciation of farm values, inequalities of taxation, the high charges between the producer and consumer, the drifting of population toward the cities, the competition due to the opening of the West, overproduction, the increase of governmental expenses, and the fact that the farmer reacts slowly to economic changes; second, poor roads, whereby the farmer is at a disadvantage in the market and is socially ostracised; third, the lack of good farming and of the ability to take hold of the new knowledge and inspiration of the day, as seen in the need of education and of business method, in the tendency to follow old lines of effort, in the lack of specialization; fourth, social conditions, comprising the relative isolation of the farmer and the consequent unattractiveness of his life, the fact that he does not appreciate his business, the great increase of expenses due to his effort to provide what may be called the luxuries of life." (1010.)

1. **Foreign and Western competition.**—Mr. WILSON, master of the Illinois State Grange, says the farmers have come into competition with the great fields opened up in the West during the past 20 years, and that the competition of foreign countries, such as Argentina and Russia, has also had quite an effect. (250.)

Mr. WEDDERBURN thinks the farmer is brought into unjust competition at home and abroad; he is compelled to compete in the open markets of the world with men who pay from 6 to 20 cents a day for labor on cheap land, and in some cases with American agricultural implements and government bounties, while at home he has to pay on a protective basis for everything he uses. Mr. Wedderburn understands that in the Danubian provinces the railroads carry export grain for very much less than any other commodity. He implies that the low rate practically amounts to a bounty affecting American farmers disadvantageously. (628, 629.)

Mr. BRIGHAM thinks the land laws of the United States have been unduly liberal, and have led to the opening of Western farms before they were needed. This has injured the farmers in the East, and those in the West themselves are now suffering from the overproduction of farm products. The grants to railways, also, have had an undesirable effect. The competition of Western lands has forced Eastern farmers to change their methods greatly, and where, on account of the distance from cities, this has been less possible, the farmers have suffered especially. (10, 11.)

Mr. SNOW, statistician of the Orange Judd Farmer, says that for the last 25 years the owners of farms in the older communities have been brought into competition with the homesteads practically given away by the Government. There has been a good deal of opposition on the part of farmers in the older sections to the Government's land policy. The public land is now generally taken up, and that competition is over. The result is a rise in the value of farm lands, and a corresponding improvement in the position of the American farmer. (240.)

Professor DAVENPORT says there has never been in the history of the world the sudden opening up of anything like such an agricultural tract as Western America. The farmers of the Mississippi Valley and the West have aimed to get maximum crops regardless of the consequence to the soil, and have thrown upon the markets of the world an immense quantity of food products raised at a minimum cost, so that it has been very hard for foreigners to compete with them, and our own Eastern farmers have been crowded to the wall. (266.)

Mr. WHITNEY, chief of the Bureau (formerly Division) of Soils in the Department of Agriculture, says that while cheap transportation has opened up new and extensive markets, it has also been the cause of the development of extensive areas of new and very fertile country, and the effect of this upon the New England States and the South has been very great. When wheat brought \$1.25 and \$1.50 a bushel, and hay was correspondingly valuable, the New England farms were profitable, and the farmers made a comfortable living, but with low prices and cheap transportation they are unable to compete on their small areas of rough land with the fertile and easily cultivated lands of the West. (865, 866.)

Mr. POWERS has no doubt that the surplus products of the West, with cheap transportation, have unfavorably affected Eastern farmers, who are suffering very much

from the competition of the West in the production of certain great staples. He predicts that this competition will be felt even more severely in the future. (175, 181.)

Mr. STOCKWELL says overproduction of wheat and corn in the West, lack of a European market, the ranches on the plains, and the beef combine left New England no profit in the old lines of farm work. The progressive farmer is now working along new lines which are more profitable. (901.)

Mr. AGER ascribes the decadence of Maryland agriculture partly to the low prices for farm products, which farm machinery has had a tendency to bring about, and to the opening up of the West. (109.)

Mr. HAMILTON says the rapid development of the West has increased the aggregate production of the country very greatly, and has changed to some extent the agriculture of different sections. It has been found that certain districts in the Far West are especially adapted to certain crops. The Eastern States have found it necessary to vary the character of their crops and raise a greater variety, taking up the culture of articles which are not easily transported for long distances. Mr. Hamilton supposes that one effect has been to bring down the prices of certain crops, such as wheat. He thinks it has not affected hay, because of the bulk, and perhaps it has not greatly affected corn. (366, 367.)

Mr. DYE testifies that the competition of other States, especially fostered by discriminations in railway rates making the cost of freight relatively cheaper from greater distances, has greatly injured all classes of farming in New Jersey. The truck farming, which superseded grain production largely, now suffers from the competition of Southern States, although this varies greatly from season to season. The peach and pear growers are in many cases finding themselves unable to make a profit and are tearing out their orchards. New Jersey farmers are no longer able, in most cases, to get the very high prices for early vegetables and fruits which they formerly received. Milk also is being carried from long distances to the cities by means of refrigerator cars, so that dairymen in New Jersey are now getting scarcely 2 cents a quart for their milk. (95, 96.)

2. **Poor farming.**—Professor BAILEY considers that the lack of good farming is undoubtedly the fundamental cause of most of the agricultural unrest. The farmer's expenses are almost necessarily increasing with the new demands of civilization, and it is increasingly more important that he intensify his methods, in order to produce the greatest possible product from a given amount of land. The farmer is not usually skilled in making money from hired labor. Various natural agencies are against him. There is a general tendency toward the depletion of available plant food in the soil rather than toward its augmentation. Insects and diseases are more serious than formerly, though the resources for combating them have also increased. (1013.)

3. **Conservatism of the farmer.**—Mr. WHITNEY speaks of a lack of business planning and management among Eastern farmers that would enable them to fit their agriculture to new conditions. Farmers are a conservative class and have not changed their methods. They have persisted in attempting to compete with the West when they should have specialized to meet the changed conditions. (867.)

Mr. AGER, master of the Maryland State Grange, says the farmers as a class have raised the same crops year after year, and have not applied business principles to farming. He thinks if the farmers understood their business as thoroughly as most other classes do their business and applied business principles to farming, they would be a great deal more prosperous. The farmers as a class have not kept up with the times. Hardly any of the butter made by Maryland farmers brings a first-class price, as it would if they made a good article. The tendency of the American farmer is to work along certain lines without regard to changed conditions. As a result, he thinks there is an overproduction of a good many things, while other things, which should be produced at home, are imported. Mr. Ager believes in the diversification of farming and the rotation of crops. (113, 115.)

Professor BAILEY thinks that the remedy for the so-called agricultural decline lies largely with the farmer himself. The farmer reacts so slowly to changing conditions that he suffers after all other businesses have become accommodated to them. This lack of quick adjustment is due partly to the natural separation of the people on the farms and partly to their diversity of interests. Farming is not one occupation, but many occupations. (1010.)

Mr. HAMMOND, a cotton planter of South Carolina, says that a low type of manhood and a slow, unprogressive condition of life are regarded as indispensable to agriculture. The active young men turn to manufactures and commerce. It is true that few industries have remained in a more rudimentary condition than the tilling of the soil; but this very state of things offers greater opportunities to intelligence, industry, and enterprise than can easily be found in more crowded pursuits. (834, 835.)

LXXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Southern conservatism and lack of managing ability.—Dr. TRUE, director of the office of Experiment Stations in the Department of Agriculture, believes that the greatest difficulty connected with agriculture in the South arises out of the conservatism of the farmer, which increases in proportion to his ignorance. The colored man is imbued with the idea that it is no use to try to raise anything but cotton, which is the only crop on which he can get money advanced. He is unwilling to venture beyond that with which he is familiar. Dr. True predicts that he will be compelled to try other things, and will find that he can live without having money advanced, and that when he is no longer at the mercy of those who make advances on crops he will be much better off, if he does not grow so much cotton. At present there are thousands of farms where the profit of the better part of the land is more than eaten up by the loss on the poorer land, where cotton is grown under present methods. (145, 146.)

Dr. CROWELL says the generation of able farmers in the South has disappeared, and a new generation has not arisen. After a man is 40 years old he can not be expected to change his agricultural ideas. Agriculture lacks directive genius and managing ability, hence capital does not go in that direction. (335.)

4. Scarcity of money, etc., in the South.—Mr. HALE, a fruit grower of Georgia and Connecticut, says there is not enough money in the South to do the business of the section. The majority of the bankers who loan money there have to get it from the North. It is difficult to borrow on real estate security because of the uncertainty of the income and of the landowner's ability to pay the interest when due, and the difficulty of realizing quickly on the land in case of foreclosure. More and more money is being offered in the South on real estate security, however, at continually lower rates of interest. From 8 to 12 per cent is usually paid on loans, and sometimes a bonus besides, but money has recently been offered at Fort Valley, Ga., at 7 per cent, on real estate security. Mr. Hale thinks it possible that the high rates of interest are due in some degree to the concentration of the demand for money into a few months of the year, during the movement of the cotton crop, from September to March. (381, 382.)

Mr. BROWN, of Georgia, complains of the high rates of interest, the impossibility of borrowing money on land, the almost exclusive cultivation of cotton, and the inefficiency of negro labor. The tariff favors manufacturers, but it is not to be considered the main source of Southern depression. (60-62.)

Mr. LOVEJOY, who is a merchant as well as a planter, believes that the condition of farmers in the South is steadily getting worse, and that this is largely due to the exclusive production of cotton and the decline in its price, and to the excessive rates of interest which farmers are obliged to pay. (75-77.)

Mr. HALE says there is too much good and cheap labor in the South. An abundance of cheap labor is rather against the success of agriculture; it results in planting too large an acreage, and in neglect of personal attention by the farmer or planter. (78.)

5. Disregard of natural conditions and markets.—Mr. HANLEY, of Minnesota, says the farmer turns from one crop to another without regard to climate, soil, markets, and other conditions, and must depend upon luck or the crop failures of other sections. When the harvest is generous its very volume assists in breaking down the price. (286.)

D. Diminution of the rate of agricultural profit.—Mr. NORRIS, master of the New York State Grange, thinks there is less money made on the capital employed in agricultural pursuits now than 30 or 40 years ago, the prices of agricultural lands and products having declined. (325.)

Mr. COLES, of New Jersey, thinks the profit on the capital employed in agriculture less than formerly. Labor costs more, for while wages are not much higher, if any, the labor is not of the same quality. (126.)

Mr. AGER, of Maryland, thinks the capital employed in agriculture in Maryland is as profitable as it was 30 or 40 years ago, because of the lower price of farm products and increased taxation. (110.)

Mr. WILSON, master of the Illinois State Grange, thinks the earnings of capital in agriculture are less than 30 or 40 years ago, because there is so much more capital vested in the same area. Land has doubled in value over a great part of Illinois in the last 20 or 25 years, but rents are very little higher. When land was worth from \$15 to \$25 an acre in central Illinois the tenant gave one-third of the crop for rent; now it is worth from \$75 to \$125 an acre, and most tenants do not give more than two-fifths. (247.)

Mr. BROCKWELL, of Massachusetts, thinks the earnings of capital in agriculture are perhaps equal to those of 40 years ago, but says they should be more; it costs more to keep abreast of the times than it did, and the farmer can not afford to fall behind. (87, 888.)

Mr. POWERS says the number of men who are seeking and obtaining farms of their own is greater to-day than ever before; this is evidence that there is relatively greater profit in farming than ever before. The percentage of profit on the capital invested may be smaller than 30 years ago, just as the rate of profit and interest has been lessened in all other industries, but the farm is, to those who understand farming, the best place to make money. (184.)

Professor DAVENPORT, dean of the College of Agriculture of the University of Illinois, says much depends upon the way capital is calculated. Forty years ago land was bought from the Government at \$1.25 an acre. The same land to-day, if good land, is perhaps worth \$100 per acre. If the farmer considers that he has \$10,000 invested in a farm of 100 acres, the returns are smaller reckoned on that capital than were the returns of 25, 30, or 40 years ago reckoned on the investment of \$1.25 an acre. Professor Davenport does not think that is the fair way to figure the amount invested unless a man has had to purchase the land at that price. The income from farming is great enough so that men are willing to pay \$60, \$75, \$80, and in some cases \$100 an acre for land. (265.)

E. Price movements.—1. Advance of the prices of manufactured articles.—Mr. MILLER, secretary of the Ohio State Board of Agriculture, replying to a question concerning articles manufactured by large industrial combinations, testifies that articles manufactured from iron and steel, and merchandise generally which farmers are under the necessity of buying, including lumber and other building material, have greatly appreciated. The prices of nails and wire fencing were increased 100 per cent; at the date of his testimony (June, 1900) the increase was perhaps 75 per cent. In some cases iron and steel articles had increased in price more than 100 per cent.

Mr. Miller attributes the recent great increase in the prices of manufactured articles both to natural and to artificial causes. The trusts, he says, have much to do with the increase of prices of some merchandise, and the conditions prevailing in the country have had much to do with it. The stocks had been exhausted during the industrial depression, and the demand being greater than the mills could furnish, the prices rose. Mr. Miller believes the prices were too low during the period of depression, and that they afterwards went too high, but were settling back to normal conditions in 1900. (615.)

Mr. BURKE says the rise in steel is not entirely a result of the trust, but results partly from the splendid crops which have made the farmers buyers and increased the demand for manufactured products. (201.)

Mr. WEDDERBURN testifies that the price of glass has increased at least 30 per cent in 2 years. Barbed wire and plain wire for fencing, which he purchased at about \$2 a hundred before the steel trust was formed, advanced to \$4, afterwards falling to \$3. Mr. Wedderburn thinks it is cheaper to split rails and put them up than to buy wire at \$4 a hundred pounds. (624.)

Mr. CLOHAN, of West Virginia, testifies that the farmers found in the 18 months preceding the date of his testimony (June, 1900) that the wire trust was very much to their disadvantage. Wire fences were largely used on account of the scarcity of timber, but the American Wire Company advanced the price from 2 cents to 4½ cents a pound, and fence building almost stopped. The price afterwards dropped to 3½ cents, but people were not buying at that price. Nails had also advanced, but not as much as wire. There was also some advance in farm implements. (602.)

Generally speaking, Professor DAVENPORT thinks the same principles have operated in all lines of production to cheapen products, although some things have increased in price within a few years. (267.)

2. Decline in the prices of agricultural products.—Mr. HOLMES says that for years the farm prices of most agricultural products, except meat, poultry, and dairy products, have been declining. (155, 156.)

Mr. BURKE, editor of the Farmers' Voice, testifying in 1899, said the farmers were paying higher prices for what they bought than four years before, but were not getting proportionately higher prices for their products, and hence were dissatisfied. (201.)

Mr. WILSON thinks there was a serious decline in the price of all grain products between 1889 and 1899. Prices were as low in 1895 as in 1899, but before that they were higher. In live stock there was not much difference. (248, 249.)

Mr. YOUNG, of South Carolina, says it takes twice as much of the products of labor to pay taxes, debts, and fixed charges as it did in 1873. He has paid 9 and 10 cents a pound for meat which he can now buy for 5 cents. (118.)

Mr. HALE, of Georgia and Connecticut, questions whether the decline in prices of agricultural products, other than cotton, has been any greater than in manufactured goods and supplies. He thinks one offsets the other. (388, 389.)

LXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. COLES, of New Jersey, says that while the selling prices of agricultural products are somewhat lower than 15, 20, or 25 years ago, the depreciation has not been as great as in the prices of land, and has not amounted to 50 per cent. (127.)

Mr. HAMILTON says the value of farm products formerly made farming a very profitable business. Owing partly to the inflated condition of the currency, the prices of farm products were good, so far as debt-paying capacity was concerned. (366.)

8. *Causes of low prices.*—Mr. BRIGHAM, Assistant Secretary of Agriculture, states that on a gold basis the prices of agricultural products have, on the whole, declined somewhat during the past 30 years. This has been largely caused by the great increase in the acreage open for production in the Western States. There has been little increase in acreage in the East. The great increase of production naturally tends to lower prices. In fact, the demand for agricultural products being so uniform, an increase of production for 1 year or for a short period of years tends to depress the price so greatly that a good crop is less profitable, taking farmers as a whole, than a poor one. The four largest crops of corn during the last 20 years were sold for \$233,000,000 less than the four smallest crops. (17.)

Mr. SPEAR, of Vermont, attributes the decline in the prices of agricultural products and in the value of farm lands to the development of the West and the largely increased and cheapened production. (407.)

Mr. WIERING, Commissioner of Agriculture of New York, says that from 1860 to 1873 all farm products brought very high prices. He attributes the shrinkage in their value since 1873 partly to the dissolution of the Army in 1865, and partly to the rapid development of new lands in the West and the decrease of the cost of transportation from them. In 1870 the freight on a bushel of wheat from Chicago to New York was 30 cents; in 1890 it was 14½ cents. In 1870 the freight on corn from Chicago to New York by rail was 28 cents; in 1890 it was 11½ cents. No such decrease has been made on the products of the New York farmer. Similar conditions in other countries seem likely to injure not only the farmers of New York, but all those of the United States. All feel and will feel the competition of the great wheat fields of South America and Australia and those that are likely to be opened in Siberia. (993, 994.)

Mr. NORRIS, master of the New York State Grange, says prices of wheat, barley, and meats declined fully 15 per cent in the 20 years previous to 1899, though in that year there was a tendency for meats to increase in price, owing to a shortage of cattle and sheep. He attributes the decline in prices to overproduction, the country producing more than it consumes. (326.)

Mr. KETCHUM also attributes the decline in the prices of agricultural products during the last 20 years to overproduction. The high price of farm products 30 or 40 years ago led to the opening up of the West and to the development of production in Russia and England, until after a while there was an oversupply. (134, 135.)

Mr. POWERS says there has been but a small decline in the prices of agricultural products which have not been overproduced, but an enormous decline where the production has increased faster than the population. The law governing prices was set forth by an English economist 200 years ago. When the product per capita is doubled, the price falls to one-fourth its former figure; if the quantity per capita is increased three times, the price will be decreased to one-ninth; doubling the per capita demand or reducing the supply one-half will quadruple the price. The capacity to consume is a factor slowly modifying prices. (186.)

Mr. HANLEY does not believe that the increase of acreage under cultivation has anything to do with the decline in prices. (279.)

Professor DAVENPORT thinks there has been no greater decline in the price of agricultural products than is covered by the improved and cheapened system of production. (267.)

4. *The recent reaction in prices* (see also IX B 9, p. CCXXII).—Mr. STOCKWELL, of Massachusetts, says there is at the present time (February, 1901) an improvement in the prices of agricultural products, and the outlook is good. (891.)

Mr. GREELEY, of South Dakota, testifying in April, 1901, says there is an increase in the price of agricultural products compared with 2 or 3 years ago, especially in beef, mutton, etc. The meat market used to fluctuate violently, but there now seems to be a steadier demand and an upward tendency in prices. Mr. Greeley attributes this to the advance in the value of land. Where land is high meat is high, for it takes land to grow meat. (936.)

Mr. MILLER says some lines of farm products, notably wool and meat products, are higher, but comparatively few farmers in Ohio have wool and beef to sell. (615.)

5. *Prices of land—Eastern States.*—Mr. HALE says there was a general decline in the price of land some time ago, both on the Atlantic coast and along the Mississippi River. There is now land within 20 miles of Washington which is cheaper than on

the plains of Kansas, and better for people to buy. There is wonderfully fine land in the immediate vicinity of Washington, with a good market; but the people have not readily adjusted themselves to new conditions. (389.)

Mr. WHITNEY says that land values in New England and the Central States have generally fallen, though in specific cases they have risen or maintained their level. (867.)

Mr. SPEAR testifies that there has been a decline of one-half in the price of Vermont farm lands in the past 25 years. The prices range from \$5 to \$50 an acre. Good meadow farms near large towns can be bought for \$30 or \$40 an acre. Very productive farms can be bought for \$5 an acre, but they are usually some distance from town and rather rough and ill adapted to the use of machinery. Mr. Spear is satisfied that there is no farm land in the West at once so productive and cheap as the land that can be bought in the East, especially in Vermont. (404, 407.)

Mr. FLANDERS, Assistant Commissioner of Agriculture, New York, thinks that since the nineties there has been a slight increase in the value of farm lands in New York, and that at least values are not declining. (999.)

Mr. POWERS says that in central New York the average price of farm land is a little less than half what it was in 1870. (178.)

Mr. DRYO, secretary of the New York Board of Tax Commissioners, thinks that the values of farm lands in New York are still declining. (1000.)

Mr. KETCHUM, of Pennington, N. J., says there has been a decline of from one-half to nearly two-thirds in the value of agricultural lands in that vicinity, except in the case of choice locations near the city. A farm within 4 or 5 miles of Trenton will bring almost double what it would be worth 10 or 15 miles away, because the farmer can retail his own milk in Trenton at 6 or 8 cents a quart, and at the same time dispose of potatoes, eggs, etc., which he takes along in the milk wagon. (135.)

Mr. COLES testifies that the price of tillable land in Salem County, N. J., runs from \$40 to as high as \$80. There are a great many farms which will not sell for much more than their buildings cost at the time of high prices. The price of farms is about 50 per cent less than when prices were highest. (124, 125.)

Mr. HAMILTON testifies that the price of farm lands in Pennsylvania in 1859 averaged \$63.27 per acre; in 1869, with an inflated currency, the average was \$90.61; in 1879 the average was \$72.68, and in 1889 it was \$53.37. (366.)

Reasons for the decline in value of Eastern lands.—Mr. AARON JONES, master of the National Grange, assigns two causes for the decline in value of Eastern lands: (1) The decline in fertility through bad management, and (2) the unnatural development of the West by land grants to railroads and by discriminating freight rates. (37.)

Mr. HAMILTON says the extension of railroads seems to have had a good deal to do with the decline in the prices of Eastern farm lands. As the railroads extended and the free fertile land of the Far West was developed the price of farm lands in the East dropped. The price was also reduced by placing on the market very nearly at the same time many thousands of acres of agricultural land appropriated by Congress to the States, and so glutting the market. Young men refused to pay \$90 an acre for land when by going West they could buy better land for from 50 cents to \$1.50 an acre, and when cheap railroad rates were offered to shippers in the Far West. (366.)

Dr. CROWELL says the depreciation of lands in the Middle and Eastern States since the continental railroads were built has been greater than is due to the opening up of the West. It is due also to the growth of manufacturing and commercial interests in the East, in which capital finds a much more remunerative field of investment than in agriculture in the same locality. Again, a young man who has inherited a farm in the East may not stay on it, because he sees that if he sells out his capital will enable him to get land in another State that is likely to increase in value with the growth of population. (340.)

Mr. DYK attributes the marked decrease in the value of agricultural land in New Jersey primarily to the decreased profits of agriculture, resulting especially from the competition of the West. This country, he says, has unduly encouraged foreign immigration and been unduly liberal in the disposal of public lands. The consequent increase in the number of agricultural workers and in the acreage devoted to agricultural products has naturally lowered prices. The low freight rates from the West to the seaboard have often compelled Eastern farmers to market their products at a loss. Bonanza farming also has an injurious effect. On all small Eastern farms machinery of the most advanced type can not be so economically used. A large proportion of farmers' sons have been brought up to a dislike of agriculture. (86, 92.)

Mr. GREELEY, of South Dakota, says that because the Western prairies were free from stones and stumps, and because of business openings, "the people got into the

habit of coming West, and they can't stop." It seems to be an instinct to go West for less inducements than would take people East. Again, careless farming made many Eastern farmers poor, and the young men preferred to go on the rich lands rather than to improve poor ones. Mr. Greeley predicts that prices of Eastern land will soon be higher, and stay high. (944.)

Mr. POWERS says the money value of lands in the West has increased because of greater profits, and that of lands in the East has decreased since 1870 because all they have been accustomed to produce has come into sharp and direct competition with the West. (187.)

Advantage to purchasers.—Professor BAILEY, of Cornell University, points out that while the decline of land values works a hardship to the farm owners, especially when they are burdened with debts that were contracted when values were high, it is not a disadvantage to those who want to buy. When farm values are low is the time to buy farms, if one desires to make a living from the proceeds. (1011.)

Mr. KETCHUM thinks the outlook for agriculture in New Jersey is favorable. Land is cheap, and a man buying a farm now is in a very different condition from the man who bought a farm when prices were high and gave a mortgage for half or two-thirds of the price. (136.)

Central States.—Mr. MILLER testifies that in the last 25 years there has been a marked decline in the price of farm land in Ohio, but confidence is being restored, and there are fewer forced sales than some years ago. Mr. Miller attributes the decline in land values to the appreciation of money and the competition of the West; the actual productive quality of the soil is greater than it was 25 years ago. Farm values in New England and New York have suffered more from competition than Ohio values have. Mr. Miller thinks that Ohio land is worth more than before the war, in the same state of improvement. There was a very considerable advance during and immediately after the war, but prices began to be more settled after the return to specie payments. The increased demand for agricultural products immediately after the war undoubtedly affected the price of farm land as well as of farm products. (614.)

Mr. BRIGHAM says the value of agricultural land in Ohio has declined materially in the older sections, where its fertility has been partly exhausted and where buildings and improvements have been allowed to run down. In northwestern Ohio there has not been much decline. The value of good farming land ranges from \$50 to \$80 per acre. (17.)

Mr. WILSON testifies that agricultural land in Illinois was higher in price in 1899 than 10 years before, but that there had been no rise within 3 or 4 years, and that land was not quite as high as it was in 1896. Land in central Illinois was worth from \$75 to \$125 an acre. (247, 249.)

Advancing prices in the Northwest.—Mr. GREELEY testifies that the money value of farm land in Minnesota and the eastern part of the Dakotas has been increasing very rapidly for the last 2 years. He attributes the increase of value principally to the fact that the population has caught up with the land and continues to increase, while the land does not, and secondarily to the ease with which money has been obtainable. He says that if men have money they can not make a mistake in buying good lands in competition with those who want to make homes. (937.)

Mr. POWERS says the price of farm lands in southern Minnesota began to advance quite markedly about 1890 and continued to advance until 1893, when the movement was checked. In northwestern Minnesota there was no advance at that time, but a checking of the movement which had been felt before that during the rapid settlement of the section. It was a period of discouragement among the farmers. Land did not show any decline, but its sale practically ceased. The panic checked for a time the sale of lands in southern Minnesota, but prices continued firm. Of late there have been many inquiries for lands and a very marked upward tendency in price throughout the State. (187.)

Mr. BUDGE testifies that farm lands in the Red River Valley have increased in value from \$5 or \$10 to \$20 to \$40 an acre. (846.)

Mr. PHOM testifies that the price of land in Cavalier County, N. Dak., ranges from \$12 to \$15 an acre, a great increase from a few years ago. The average for the State is lowered considerably by the low prices farther west, and even for the district along the Red River Valley is not as high as the figures given. (789.)

Mr. JUMPER says the average South Dakota farm will sell for from \$600 to \$1,000. If it has been well taken care of it will sell for twice that much. There has been an appreciation of 60 per cent in 3 years. In September, 1900, Mr. Jumper sold a farm of 300 acres, near Aberdeen, for \$3,500, which he had tried to sell 2 years before for \$2,000. The farms are being bought chiefly by farmers for their sons, and now and then by a farmer from another State. (740.)

Southern States.—Mr. WHITE says it would be difficult to make a comparison between the prices of land in the South to-day and before the war, because lands were not generally for sale before the war; the owner did not need money and would not sell at any price. After his death the family moved away, and the land has been cut up and sold off. Mr. White supposes that land would bring a greater price in money before the war than now. (423.)

Mr. HALE testifies that land values have been steadily diminishing everywhere east of the Mississippi for the past 25 years, but he thinks no more so in the South than in other sections. Many plantations that were once worth \$40 or \$50 an acre have declined to \$5 and \$8 an acre. Cotton lands suffered very materially after the war; then there was something of an increase in the price, followed by a decrease in the last few years. Mr. Hale says, however, that in his section of Georgia there has been a rather steady but slight appreciation in agricultural values during the past decade, which he attributes to the diversification of crops, and especially the development of peach culture. (382.)

Mr. WEDDERBURN says the value of agricultural property is not kept up in Virginia except under exceptional circumstances. In counties adjoining Washington, valley counties, and some sections where mining industries have been established and many people have come, land has increased in value; but as a rule, outside of these special localities, the value has diminished. Mr. Wedderburn attributes the decline to two causes: (1) the decline in prices of agricultural products, and (2) an insufficient population, white labor being kept away to a certain extent by the negro labor. (622.)

Mr. Wedderburn says the price of land between Washington and Leesburg, Va., generally ranges from \$100 to \$125 an acre. In the tobacco portion of the State thousands of acres were for sale a few years ago at less than the cost of the improvements. Mr. Wedderburn bought land there at from \$2 to \$10 an acre, and thinks the same could still be done. Around Danville, where they have gone into the bright tobacco culture, he supposes lands have gone up materially. The valley lands have always been high, running from \$25 to \$100 an acre, according to the distance from the railroad. Loudoun County land runs from \$40 to \$50, and perhaps \$60 around villages and towns. Lands in Prince William County, within 30 miles of Washington, have sold at auction in the last few years for less than \$1 an acre. (623.)

Mr. Wedderburn says timber land near Bristow and Nokesville, Prince William County, lying 5 or 6 miles from a station, was bought for \$2 and \$3 an acre, and after the heavy timber was cut off, was sold for \$1 an acre or anything it would bring. (623.)

Mr. CLOHAN, of Martinsburg, W. Va., testifies that land in that locality is worth fully as much as it was in 1880. The prices are not as high as they were in 1868 in inflated currency, but it is worth as much for farming. Old men in Berkeley County say that land in that section has been of a certain fixed value for nearly 100 years. The best land would now bring \$50 or \$60 an acre. The farms that are on the market are the heavy limestone soils not particularly adapted to the growing of fruit, but splendidly adapted to grain and grass. Before the war this class of land was sold at \$40 and \$50, about the present prices. (600.)

Mr. NALL testifies that agricultural lands in Kentucky are not as valuable—that is, not as salable—as they were some years ago. He attributes the decline, however, largely to the improved purchasing power of money; going back 25 years, he thinks that the land would bring less in gold than now. (811.)

Mr. Nall testifies that in the blue-grass section of Kentucky the prices of good farm lands range from \$30 to \$60 an acre, or near the towns \$40 to \$80 an acre. Fancy places will sell from those prices up to \$150, according to improvements. There are a few sections in the western part of the State where the values would nearly equal those of the blue-grass section, but in most counties improved agricultural lands can be had at from \$10 to \$20 an acre. In the mountain section the amount of timber and the mineral prospects contribute largely to the selling value of land. (811.)

Mr. WHITE testifies that land in North Carolina in a state of cultivation will sell for from \$5 to \$30 an acre; \$25 is called a very good price. Plenty of land can be bought for from 50 cents to \$3. Good farm land will rent for \$3 or \$4 an acre per annum. Six years' rental will buy arable land; woodland can be bought for what it would rent for. (422, 423.)

Mr. HAMMOND, a cotton planter of South Carolina, says that before the war the usual price of average land was about \$10 an acre. Near the towns it has risen recently to \$30 or \$40 an acre, but remote from the towns it has fallen to \$2 or \$3. (828.)

Mr. PEEK, of Conyers, Ga., testifies that there has been a fall in the price of real estate for a number of years, but during the 12 months preceding the date of his testimony (March, 1900) prices had been steady, owing to a demand for real estate. The average value of land in his county was \$20 an acre. (460.)

Mr. STEVENS testifies that the value of agricultural lands in Georgia has greatly advanced since 1897. (915.)

Mr. NUNNALLY testifies that improved lands in Georgia are worth from \$10 to \$20 an acre. (457.)

Mr. REDDING testifies that improved farms can be bought in Georgia for from \$5 to \$10 an acre. Near the towns the prices are \$20 and \$30, but there would be no difficulty in buying a very fair farm, with a good house and in a good location, at \$10 an acre almost anywhere in Georgia. The gullies are generally filled up, and people are making fair crops. Mr. Redding does not know a single place in the State that can be called abandoned, though there are some old farm estates locked up in some way. (450.)

Mr. POOLE testifies that before the war land in Alabama was worth from \$25 to \$100 an acre, but after the war the value diminished very rapidly, and for a number of years there was no demand. The citizens were very poor. Mr. Poole estimates that the lands fell to an average of \$10 an acre, but says that within the past decade they have more than doubled in value; lands worth \$10 ten years ago are now worth from \$20 to \$25. (922.)

Mr. Poole says that in the southern part of Alabama there are large virgin pine forests, and the increase in the price of labor has stimulated the building of saw-mills all over southern Alabama. The pine lands have increased in value 100 per cent in the past decade. The timber is generally transported by rail, but there are several rivers. Mr. Poole says Alabama has some of the finest pine lands in the United States. Lumber is shipped all over the world from Mobile and Pensacola. Where there are ordinary facilities for the transportation of timber, the lands bring from \$3 to \$10 an acre. (922, 923.)

Mr. GAGE testifies that the value of land in the Memphis district, particularly in Arkansas and Mississippi and the rich bottom land of the hills, has increased in value a great deal within a few years. (492.)

Mr. KYLE, of Panola County, Miss., testifies that there has been an increase in the value of land in his county in the past decade, the price of cotton having improved. (465.)

Mr. BALCH, of Little Rock, Ark., testifies that prices of Southern farm lands were very low in 1893, 1894, and 1895, but have advanced very materially since the return of normal conditions. Mr. Balch represents the owners of timber lands which have advanced from \$1.25 in 1896 to \$6 and \$7 early in 1900, the area on the market having diminished. (495, 496.)

Mr. NORFLEET, of Tennessee, testifies that unimproved Mississippi bottom lands are bought at about \$6 or \$8 an acre. A railroad acquired about 600,000 acres of land and fixed a uniform price of about \$6 an acre, giving 5 years' time for payment in installments, at 6 per cent interest; and private citizens sold at about the same price. Usually 10 or 20 per cent is paid down. Sometimes there has been a disposition to sell this land without any payment down, because everything done upon it improves its condition. (486.)

California.—A statement by the president of the State Board of Trade of California, presented by Mr. TURNBULL, sets forth that in 1890, when the prices of fruits were very high, it was not unusual for orange growers to net \$500 an acre, and fruit growers generally could show good interest on orchards valued at \$1,000 an acre. Fruit growing gave a fictitious value to the available fruit lands. Land devoted to general farming went to enormous figures—\$100 or \$200 an acre. Land can now be bought at one-third, or even less, of the prices of those boom days. In those days large tracts were held by individual owners who would neither sell nor subdivide. Now the great ranches are being broken up and offered in small tracts at reasonable prices. There never was a more favorable time to secure homes in California at fair prices than at present. (988.)

Mr. NAFTZGER says that probably nowhere else on the continent are the prices of land so divergent as in California. There are vast areas of broken mountain lands and desert lands that are practically worthless. Grazing lands are worth from about \$2.50 to \$10 an acre. Lands upon which cereals can be grown are worth from \$15 to \$50 an acre. Fruit lands with water are worth \$100 to \$400 an acre, depending upon the reliability of the water supply, the nearness to markets, the quality of the soil, the character of the fruit they will produce, the freedom from frosts, etc. (961, 962.)

F. The industrial revolution in agriculture.—1. Beneficial effects of improved machinery.—Mr. KETCHUM, of New Jersey, says that improved agricultural machinery has been of great benefit to farmers. He does not know how they could continue farming without it. (135.)

Mr. DYE says improved machinery has had very great influence both in the East and in the West upon the conditions of farming. It has especially enabled the opening of enormous territories in the West which could not have been economically worked otherwise. (96.)

Mr. PROM, of North Dakota, says machinery has facilitated the raising of crops and to some extent compensated for the decline in the price of wheat. (793.)

Mr. STROCKWELL says improved agricultural machinery does away with a great deal of labor and makes possible the production of larger crops at a smaller cost, thus giving a margin of profit. (895.)

Mr. GEORGE says that improved machinery has made possible the thorough cultivation of the soil, increased the yield, and lessened the cost of production. (223.)

Mr. HALE, of Georgia and Connecticut, says there is no question that machinery has increased production and reduced the cost of production, and will result in the using of less land, more intensive cultivation, and better results. (396.)

Cheapening of production.—Mr. MILLER, secretary of the Ohio State Board of Agriculture, says the farmer can produce more cheaply than 25 or 30 years ago, by reason of improved machinery and appliances. (617.)

Mr. GEORGE says the cost of production in agriculture has greatly decreased with the development of modern facilities. He estimates that it costs not more than one-fourth as much to produce a bushel of wheat as it did 40 years ago when wheat was cut with a cradle. (220.)

Mr. AGER says that improved agricultural machinery enables the farmer to produce a great deal more at less expense than formerly. He thinks that with the amount and class of labor available in Maryland it would not be possible to carry on agriculture without the assistance of machinery. (115.)

Mr. CLOHAN, of West Virginia, thinks there has been a decrease in the cost of production of farm products within the past 20 years by the use of labor-saving machinery. (600.)

Mr. HOLMES says the farmer is using better and more labor-saving machines and implements than ever before, and the human labor element in agricultural production is probably diminishing relatively to the amount of the product. In the case of corn, in 1855 the shovel plow was used for marking rows and for cultivating, and the hoe for planting. The stalks were cut with knives, and the corn was husked and shelled by hand. In 1894, plowing was done with the gang plow and corn planter, a machine was used for cutting and binding the stalks, and a combined husking and fodder-cutting machine and a steam corn sheller were used. The investigations of the Department of Labor show that machines and improved implements have reduced the human labor cost per bushel from 35.77 to 10.57 cents, or 70.5 per cent, and the time of human labor from 274 to 41.3 minutes, or 84.9 per cent. Striking reductions in the time and cost of human and animal labor in the production of other crops are also shown. Mr. Holmes calls attention to the great difference between the time when 20 minutes of human labor were required to husk a bushel of corn with a husking peg, and 102 minutes to haul the stalks to a barn and cut them into fodder, and the present, when 17½ minutes are sufficient to haul the same stalks to a husker and husk the corn and at the same time cut the stalks into fodder by steam; "and there was a transition from one agricultural age to another when a man ceased to expend 100 minutes of labor in shelling a bushel of corn by hand, and employed a steam sheller by which a bushel of corn is shelled in a minute and a half. When farmers reaped their wheat with sickles and bound the straw by hand, hauled the sheaves to the barn and thrashed the grain with flails, these operations, applied to 1 bushel of wheat, required the labor of 1 man for 160 minutes, whereas this work is now done, by the use of a combined reaper and thrasher operated by steam, with 4 minutes of human labor." (157.)

Professor DAVENPORT testifies that the 8-foot-cut mowing machine not only reduces the cost of mowing by more than half in comparison with the 4-foot-cut machine, but the life of the machine is doubled, because it is no harder on the machine to cut 8 feet of grass than 4. The cost of producing the hay crop has been greatly reduced by the invention of a rake that delivers the hay in a continuous stream at the side, so that it can be followed immediately by a hay loader. Professor Davenport says the same is true of the other crops. The Breed weeder not only cultivates corn four times as fast as it was formerly done, but cultivates it better and replaces several cultivations by the old method, thus cheapening production. (267.)

Saving of labor.—Mr. AGER, of Maryland, testifies that with improved machinery farmers do not require the amount of labor they formerly needed. Where 5 or 6 men were formerly employed during harvest, 1 or 2 are now sufficient. The machinery also makes the work lighter. (104.)

Mr. CLOHAN, of Martinsburg, W. Va., estimates that there has been a diminution of one-fourth in the number employed in agricultural labor in his section of that State within 15, 20, or 30 years, due to the introduction of such improved machinery as self-binders, mowers, hayrakes, hayforks, etc. Fifteen years ago a good deal of meadow was cut by the scythe, and grain was all cut by the cradle within the limits of time mentioned. Another effect of improved machinery is that the farm laborers do not have as regular work as they did 15 or 20 years ago; the work is hurried through as rapidly as possible. The drudgery of farm labor has been diminished by the present methods, however. (591.)

Mr. HAMMOND, of South Carolina, says that the reaper, the mower, and the cotton planter have displaced a great deal of labor. The more skilled and reliable laborers get perhaps 25 per cent more than the common laborers; but this advance does not make up for the wages formerly paid to cradlers, hay cutters, and cotton-seed sowers. Cradlers were paid more than double what is now paid for the same work done by machine. (816.)

Mr. NUNNALLY estimates that there has been a diminution of one-third in the number of farm laborers in Georgia, although the population has steadily increased. The work is now done mostly by men, the females being employed only in light work, such as chopping corn, hoeing, and picking cotton, while a large majority remain in the house the year round. Work is so facilitated by machinery that there is less necessity for manual labor. The work of 6 or 8 men is now accomplished by 1. The reaping hook is a dream of the past, and the McCormick reaper and 2 mules do the work of 8 good men. (454.)

Dr. CROWELL says improved machinery has reduced the farmers' wage bill very considerably, and increased the size of farms. (344.)

Mr. SPEAR, of Vermont, says farming has become less drudgery and more of a business in consequence of improved machinery and improved methods. (402.)

Mr. WILSON, of Illinois, says improved machinery has done away with the drudgery of the farm, though there is still hard work to be done. (243.)

Mr. MORAN, president of the National Grain Growers' Cooperative Association, estimates that 1 man driving a self-binder with 3 or 4 horses can accomplish as much in a day as he could do with a cradle in 5 days. (711.)

Mr. M. F. GREELEY, secretary of the Board of Regents of Education of South Dakota, says that when he first worked on a farm it took 5 binders to follow a machine, 1 man to rake off, and 1 to carry the bundles together; now a hired girl frequently drives a machine that does it all. (938.)

Mr. BRIDGE, of North Dakota, says it would be impracticable to settle up the country and raise wheat without machinery. Machinery has removed the drudgery from farm life to some extent and farming is now about as easy as anything one can do. The only drudgery about the farm is taking care of the barn. (852.)

Mr. BRIGHAM, Assistant Secretary of Agriculture, and Mr. AARON JONES, Master of the National Grange, agree that the introduction of improved agricultural machinery has not decreased the price of farm labor, although it has somewhat decreased employment during harvesting and haying. The work has been rendered much less severe by the use of machinery. (5, 33.)

Intensive culture.—Mr. KETCHUM, of New Jersey, thinks the cost of production of a crop is about the same now as it was in 1860, notwithstanding the use of improved machinery. Farm labor costs a great deal more and it is necessary to use commercial fertilizers. Machinery has brought about a more intensive farming in New Jersey, so that about the same amount of labor is employed as 30 or 40 years ago. (132, 136.)

Professor DAVENPORT thinks the impression that agriculturists would be crowded out of employment by improved machinery was entirely groundless. The introduction of machinery has vastly extended agricultural operations. It has extended the acreage under cultivation, and has increased the amount of labor per acre bestowed upon the land. He does not think it has decreased the total number of men employed on the land. The cheapness of machine production has enabled farmers to intensify their agriculture; they employ about as many men as they ever did, and do more things. (256, 267.)

Diversification.—Mr. COLES, of New Jersey, says that improvements in agricultural machinery have been the cause of more diversified crops. (125.)

Mr. NORRIS, master of the New York State Grange, thinks machinery has not decreased the demand for labor on the farm, but has opened up new avenues of industry that have given employment to those formerly engaged in hand labor, and so improved the condition of labor. (320.)

Educational effect of improved agricultural implements.—Mr. POWERS regards improved farm machinery as an educational factor—one of the great factors in the elevation of agricultural labor; it has stimulated greater intelligence on the part of laborers and otherwise improved the intellectual status of the American farmer. He regards the comparatively slight use of machinery in the South as one explanation of the lack of agricultural progress in that section. (171, 183.)

Mr. STOCKWELL, of Massachusetts, says the natural effect of improved machinery is to raise the quality of labor, more intelligence and skill being required for its profitable use. Yet this is offset somewhat by the different quality of labor seeking our shores. (884.)

Professor DAVENPORT says the use of improved machinery necessitates a higher grade of agricultural labor; at least some of the labor employed on a farm should be of higher grade, though not necessarily all of it. On the other hand, there is perhaps less manual skill on the part of farm laborers than formerly. There is no call for expert cradlers, expert binders, etc. (256.)

2. Disadvantages of machine production.—Mr. M. F. GREELEY, of South Dakota, says the use of improved machinery, with the opening up of so much easily tilled prairie land, has tended to reduce the price of grain, and it has ruined many a man to buy machinery when he could not pay for it and did not need it. (938.)

Mr. MORAN concedes that machinery has reduced the cost of production to some extent, yet in the days of the cradle it appeared to be easier for the farmer to pay his debts than now; the hours of labor also are longer than in the old days. (711.)

3. Agricultural implements in the South.—Mr. POWERS says machinery is not used to so large an extent in the South as in the North, chiefly because the negro laborer has not been educated up to its use, and also because corn is raised less in the South than in the North. (171.)

Mr. NUNNALLY says the Southern farmers can not trust their tenants with machinery, except one or two simple things like cotton-seed planters. Where machinery is used the owner of the farm operates it with the assistance of his family and one or two hired hands. (456, 457.)

Mr. WEDDERBURN says the farms of Virginia are not large. The farmers use the mower, reaper, thrashing machine, and grain drill, and buy the latest improved plows and cultivators. In the larger wheat-growing sections, where a man raises 300 or 400 bushels, the binder is used. (625.)

Mr. LOVEJOY says there is very little improved machinery used on the farms of Georgia. Not even sulky plows or reapers and binders are employed. The whites are somewhat better able to adapt themselves to machinery than the negroes, but even among them there is so little mechanical skill that they scarcely know how to put together and repair machines. Moreover, where labor costs only from \$6 to \$8 per month, it is cheaper than machinery for many kinds of work. (79, 80.)

Mr. STEVENS testifies that almost every kind of improved machinery has been introduced in Georgia, and within 2 years the increase in the use of machinery has been particularly marked. The management of improved machinery requires a more intelligent class of laborers than formerly, and has been accompanied with an improvement in methods of cultivation as great as in other sections of the Union. The introduction of improved machinery has made it possible to produce all crops at very much less expense, and therefore at greatly increased profits. (906, 915.)

Mr. REDDING testifies that 2-horse cultivators that will plow out a row of cotton at one trip have been introduced to some extent, but are not used largely in Georgia. He thinks improved machinery will come into use with the increased cultivation of cereals. He believes that machinery benefits the farmer, but not the laborer. (453.)

Mr. POOLE, of Alabama, says it is hard to teach the colored laborer the use of improved methods of agriculture; consequently the large farmers of Alabama often pursue very much the old system employed by their fathers and grandfathers. New machinery is being brought into Alabama very generally, however. Some years ago all the cotton was sown by hand; now cotton planters are always used. The oats and the wheat grown in the Tennessee Valley were formerly cut with the old-fashioned cradle; now the McCormick binder and reaper are generally used. There are numerous labor-saving machines, such as cultivators, stalk cutters, etc. The planters have dreamed of a cotton picker, but have not been able to obtain anything successful. The departure of the young laborers to the mines forces the farmers to resort to these labor-saving machines to supply the deficiency, but so far there has been an abundance of labor to meet all demands. (921.)

Dr. STRUBBS, director of the Louisiana experiment stations, while admitting that very little improved machinery has been introduced in cotton culture, declares that in cane and rice culture Louisiana is up to date. During the past decade the rice growers of Louisiana have adopted the most improved machinery that has ever been used in growing rice. It is the process used for wheat raising in the West, with

made modifications. The land is broken with gang plows and harrowed with enormous 4-horse harrows, and the rice is seeded with grain drills or broadcast seeders, and harvested with self-binders and steam thrashers. The result is a very low cost. Dr. Stubbs cannot see how there can be a profit, as is claimed, in rice culture in Hawaii, where the Chinese transplant it by hand in water. • (770, 772.)

Mr. HALS testifies that where improved machinery is used in the South it increases the wages of those who are able to handle it. (376.)

Mr. POWERS believes that machinery will ultimately be applied to the staples of the South. When the Southern negro has acquired a mechanical education, and when the cotton grower has the same grade of intelligence and knowledge of mechanical principles as the wheat raiser of the North, there will be the same progress in machinery and with it the same general advancement. (172.)

4. Cessation of mechanical progress.—Mr. HAMMOND, of South Carolina, while declaring that the inventors of agricultural machinery have created a new agriculture that has filled the earth with plenty undreamed of before, continues:

"But interest and progress in the mechanics of agriculture seem to belong to a period that is past. The gin is more than a century old. Cultivators, horse hoes, and seed drills were used in this country before the Revolution. Steel hoes were manufactured and sold cheaper in 1831 than they can be sought for to-day. It is more than a generation since the American reapers, mowers, and thrashers took the first prizes at the Paris International Exposition of 1855, and since 144 bushels of wheat per acre was cut and thrashed daily on the Huffman ranch in California, a performance which could not be excelled, even if equaled, by the implements and machinery now in use. The period of greatest prosperity and development in agriculture was during the golden decade of 1850-1860. The increase in the value of farm implements and machinery in those 10 years was 62 per cent. In the two succeeding decades, notwithstanding the growth of the population, the vast areas of fresh lands brought under cultivation, and the enormous additions to the agricultural products of the country, the increase in the value of the implements and machinery employed on farms barely equaled the increase of the single decade preceding. The value of agricultural implements manufactured in the United States increased 150 per cent between 1850 and 1860 (we were supplying the trade of the world), between 1860 and 1870 the increase was only 122 per cent, and between 1870 and 1880 it fell to 5 per cent. The manufacture of farm implements has fallen more and more into the hands of large concerns, which have bought out smaller ones, and hold a monopoly of the business. One company, a harrow trust, has in recent years bought up 21 other companies and advanced the price of their products as much as 31 per cent. These trusts possess themselves of every new patent, holding it for their exclusive use, or what is worse, suppressing it, to avoid the additional expense of new and improved models. Experts declare that it would pay many manufacturers to give away their machines for the profit to be found in selling duplicates of parts that break or wear out from faulty construction."

Mr. Hammond does not know of any improvement that has been introduced in the last 30 years except the corn harvester and shredder. The lack of advance is not for lack of effort, as is shown by the records of the patent office. In the list of patents for the 3 months ending June 30, 1893, 25 improvements in plows and 21 in planters are entered. But the advances that are made are not brought to the notice of the farmers. The dealers in agricultural machinery prefer to go on in the old ruts. The Department of Agriculture gives no attention to agricultural machinery, and the agricultural colleges and experiment stations imitate it. Among the 491 officials employed in 1892 in the 61 colleges and 52 experiment stations of the United States, only 5 persons were concerned with the mechanics and engineering of agriculture. Only about 6 per cent of the courses of instruction had to do with agricultural mechanics. If the Department of Agriculture would establish a division of mechanics, and would in its bulletins give information of mechanical improvements, the mechanical progress of agriculture would be more like that of other occupations. (816-819, 830.)

5. Prices of agricultural implements.—Mr. MORAN says a self-binder costs the farmer from \$125 to \$135, bought of course on time, with interest at 7 per cent. The first self-binder Mr. Moran purchased cost \$300, and \$15 for freight, with 7 per cent interest added. In the early days, on the other hand, the farmer used a cradle which cost only a trifle. (710.)

Mr. POWERS says a reaper which was not a self-binder cost in 1870 about \$350 or \$400; a self-binder is now bought for \$125. A better plow can now be bought for \$12 than for \$28 in 1870, and so on with other machines and all other articles purchased by the farmer. When a reaper cost \$400 a man had to go with each machine to teach the people to use it—a high-priced mechanic who had to spend, on an average, 10 days with every purchaser. That added at least \$100 to the price of a first-class reaper. When a great many farmers have been educated in this way they, in turn, teach the other farmers, and that expense is eliminated. (183, 187.)

Mr. WOODMAN testifies that plows and most steel implements are higher than they were 3 to 6 years before the date of his testimony (June, 1900). He states, on the authority of a Congressional report, made probably during the Fifty-second Congress, that some machines were at that time selling in Europe and Canada at considerably lower prices than in this country. (625.)

6. Farm implements for the South American trade.—Professor DAVENPORT says American manufacturers of farm implements cater to the South American trade by making the kind of machines wanted there. Some of the regular designs can not be used in South America because the laborers are not able to operate them. The machinery must be comparatively simple. (270.)

G. The new agriculture.—1. Recent improvements.—Professor DAVENPORT declares that farm life and farm labor have taken on a new aspect within the last decade. The drudgery of the farm has been wonderfully lessened, and more skilled methods introduced. Only within the last few years have farmers commenced to take daily papers and concern themselves with public questions, or to feel that other occupations are interested in agriculture. Even yet the average farmer has no conception of the light in which agriculture and agricultural people are esteemed by the leading men of the country. (258.)

Professor Davenport remarks a rising grade of intelligence among farmers. Typical American agriculture is a profession as truly as law, medicine, or the ministry. The agriculture of America is represented especially by the great section west of the Allegheny Mountains and east of the Rockies, where the population is made up of the New England type, the Dutch from Pennsylvania, the old English aristocracy from Virginia, some of the Southern element, and, in the north, Scandinavian immigrants. This mixed population has no parallel in the world. (259.)

Professor Davenport sums up by saying that the condition of the farmer is better than he has ever known it before and is steadily improving. The general tendency has been upward all the time. (267.)

2. The passing of agricultural discontent.—Mr. AARON JONES, master of the National Grange, testifies that the period of discontent among farmers is passing away, owing to the increased comforts of farm life and the better knowledge of the farmers as to the relative advantages which they enjoy. The farmers' organizations have taught their members to understand the value of their homes, their food, their horses and carriages, etc. (34.)

3. The future of agriculture.—Mr. KETCHUM's opinion is that supply and demand will equalize themselves, perhaps within the present generation, and that when they are brought nearly to a balance farming will be as good as any other business. (135, 136.)

Mr. STOCKWELL says the agriculture of New England is improving. Wealth sees the coming change and invests for future profit. The farmer is not discouraged, but looks forward to the coming prosperity. He realizes the dignity and importance of his calling, and sees that through cooperation and united effort much can be accomplished to improve and advance his position. (904, 905.)

II. FARM OWNERSHIP, TENANCY, AND INDEBTEDNESS.

A. Acquisition and ownership of farms.—1. By farmers (see also, as regards negroes, IV C 4, p. cxxxiv).—Mr. POWERS says that while only a small proportion of the earlier immigrants to this country were able to become farm owners, a large proportion of the later immigration has risen to ownership, assisted by liberal land laws. (171.)

New Jersey.—Mr. COLES, of New Jersey, says there are a number of instances in his vicinity of persons whose parents were farm laborers acquiring farms of their own. (124.)

Minnesota.—Mr. MORAN, of Graceville, Minn., declares it almost impossible for a young man to purchase a home at the present prices of land, go in debt for the land, and also for the necessary implements, horses, and cattle, and get out of debt within his natural life. In his opinion a young man who starts with nothing as a farm laborer can not generally acquire a farm of his own. Mr. Moran admits that there are some instances, however, where wheat land can be bought and paid for during the purchaser's lifetime. (710.)

North Carolina.—Mr. WHITE says a surprisingly large number of colored people in North Carolina have purchased little plots of ground. Mr. White thinks this is true also of the people in the western part of the State, who are largely white. These mountaineers, as a rule, are poor people, but possibly are not as poor as the colored people in the eastern part of the State. The wealth of the State consists in small possessions. (420, 421.)

Mr. GRAHAM, of North Carolina, who has been engaged in selling property as an agent for 20 years, testifies that men who contract to pay for property in 3 years frequently have to be carried 10 years. The home is lost only in a few instances; public sentiment condemns it, and the poor returns from farming do not make the sellers

anxious to get possession of the land. In his experience 2 men out of about 40 surrendered their purchases. (436.)

Georgia.—Mr. REDDING thinks the white farmers of Georgia generally own the land they farm. (448.)

Mr. STEVENS says that by the census of 1890, out of 352,059 families in Georgia, 110,639 were reported as owning their farms and homes, and the proportion owning free of encumbrances was nearly 97 per cent. There were 241,400 families hiring homes and farms.

A good many of the tenant farmers of Georgia are buying land at from \$3 to \$7 an acre. They have from 5 to 7 years in which to pay for it, and so long as a man keeps up his improvements and pays the interest (8 per cent by special agreement) there is no tendency to force him to pay the principal. (912, 914.)

Mr. NUNNALLY testifies that the young men of his section of Georgia are very anxious to procure farms, and work hard to that end. (457.)

Mississippi and Tennessee.—Mr. KYLE is of the opinion that the white farmers of Mississippi generally own their homes. (469, 470.)

Mr. HILL, of Memphis, estimates that 80 or 90 per cent of the white farmers in that vicinity own their farms. The mortgages have been greatly reduced owing to the advance in cotton. (503.)

2. *As investments.*—Mr. GEORGE says that in Illinois many of the best farms have been purchased as investments by bankers, merchants, and the more successful farmers. The large farms are going into the hands of men who have money, who hold them for a rise in price or rent them for \$5 or \$6 an acre. (221.)

B. Farm mortgages.—Professor BAILEY, of Cornell University, remarks that in many cases the mortgage represents the purchase money of the farm. Where it does not, it is rather an indication of unfortunate local conditions or of poor individual management than a fundamental cause of general depression. (1012.)

Mr. POWERS says there are three times as many mortgages foreclosed in the East as in the West, and that the question of debt is ten times as great in certain parts of New York and New England as in the Western and Southwestern States. (175.)

Mr. WETTING, Commissioner of Agriculture of New York, says that as a result of the high prices of farm products from 1860 to 1873 farm lands in New York were very highly valued. Many farms were bought on time at high prices and mortgaged, and when prices fell and the value of land shrank many farmers lost what they had invested. (993.)

Mr. COLES, of Salem County, N. J., testifies that farmers in that section are occasionally sold out by the sheriff. In the great majority of cases they have been dragged down by buying at high prices years ago. (129.)

Mr. FROM, of Milton, N. Dak., testifies that the majority of farms in that section are mortgaged, though not heavily. The mortgages are being paid off, however, and many that could pay them off prefer to keep a mortgage on the farm and keep the money to buy extra land. The average interest on farm mortgages is 8 per cent. Many mortgages were made to acquire more land. Mr. From thinks it was wise for the farmers to borrow for that purpose. He does not look upon the great number of mortgages as an indication of adversity; they aid the development of the country, which could not have developed on a cash basis.

Mr. From says most of the farms in his section are bought on credit. Lands can be bought on crop payments, or for so many thousand bushels of wheat. In the crop-payment plan the purchaser binds himself to pay one-half the grain he raises every year, retaining the other half for seed and expenses; thus he can gradually pay for the farm. Mr. From pronounces this an excellent plan. (790.)

Mr. JUMPER, of Aberdeen, S. Dak., estimates that two-thirds of the land in the northern half of South Dakota has gone into the hands of mortgage companies. Many of the original farmers have become tenant farmers by that process. A good many farmers who had filed on a quarter section and had perhaps taken up a preemption undertook to extend their farms and purchased other lands by giving a mortgage on all they had, and during the time of the droughts and the low prices of wheat they had to lose some of their farms. A good many of them still rent these farms. At the time of the early settlement of that part of the country, from 1883 to 1886, many young men and young women took up claims and lived, or pretended to live, on them 6 months, got mortgages on them, and then left and never came back. All the land owned by the mortgage companies is on the market at reasonable prices, and farms are often bought back by those who lose them. The mortgage companies are largely located in New England, New York, and New Jersey. (733, 734.)

Mr. JUMPER says that 10 years ago it was easy to get a 10 per cent farm mortgage in his section; now it is hard to get a 6 per cent farm mortgage. Practically no mortgages are being foreclosed. (740.)

Mr. MORAN estimates that 50 per cent or more of the homesteads taken up in his section (western Minnesota) are already mortgaged. (710.)

Mr. M. F. GREELEY says there is too great a tendency in the West to run into debt. A man who would not go in debt in the East will unhesitatingly do so in Dakota. In a good many cases enterprising young men who have a few hundred dollars can get a piece of land, going in debt for the balance, and make a home and pay for it; but that is the only case in which Mr. Greeley approves of mortgaging a farm.

Mr. Greeley says that in many sections formerly heavily mortgaged the mortgage has nearly disappeared. (935.)

Mr. STOCKWELL says there is hardly a town in New England that has not many reminders of the hard times experienced by the West, that rest as a nightmare on the farm-mortgage companies of New England. (892.)

Mr. CLOHAN, of West Virginia, testifies that there are a great many men in his locality who were badly involved after the war, or had bought at war prices, who kept on struggling and paying their interest up to about 1893, when the panic forced a great many into liquidation. That, together with the settling up of old estates already in liquidation, has caused many changes in real-estate ownership within a few years. (593, 599.)

Mr. YOUNG says the original landholders of South Carolina got in debt soon after the war. They all became involved when cotton dropped suddenly in 1866. Their land has nearly all been transferred to other hands, and is now being lost by the second parties. The small farmers of South Carolina are being crowded out; their farms are being mortgaged more and more each year, until finally they have to give up the deeds. They borrow usually of the country merchant or cotton factor, who in turn borrows from the North. Mr. Young thinks it is only a question of time until most of them will be drawn into the towns. (120.)

Mr. PEEK, of Georgia, testifies that a great many people in that part of the country have had to mortgage their land and lose it. He says the majority of farmers are now homeless, because of the loss in raising cotton. (458, 460.)

Mr. LOVEJOY estimates (June, 1899) that half the planters in Georgia have mules and lands mortgaged as a result of the low price of cotton. (75.)

Mr. POOLE says that 10 years ago the plantations of Alabama were largely mortgaged, but the mortgages have been rapidly paid off. He estimates that not over 15 or 20 per cent, or 25 per cent at the very outside, of the lands of Alabama are now mortgaged. He characterizes the past decade as an era of prosperity in Alabama. (922.)

Mr. NORFLEET, of Memphis, thinks the greater part of land owners in that vicinity are mortgaged for a smaller or larger amount. The mortgage loan companies very frequently find that they have loaned too much on a tract of land. Quite a number of loan and mortgage companies with agencies in Tennessee have thus acquired the ownership of land and are renting it. (492.)

C. Tenancy.—1. **Extent.**—Mr. POWERS says the tenancy that involves large holding of land by capitalists of great wealth and a permanent tenant class practically never existed in this country, except in New York and some other parts of the East. In New York, farms were formerly leased for long periods of time, as 100 years, and tenants could not become farm owners. The system bred discontent and the question became an issue in politics. The new State constitution adopted in 1846 forbade the leasing of farm lands for more than 12 years. In certain parts of Illinois and some other sections there are a few large tracts of land operated by tenants and owned by capitalists who will not sell it, but these places are few in number. (173.)

Mr. GREELEY, of South Dakota, says capitalists, seeing that land is going to be valuable—that population will increase, while land will not—are buying up small farms wherever the owners are so shortsighted as to part with them, or are getting them through mortgages, and putting on tenants. This practice is growing with alarming rapidity in the richer portions of Minnesota, the Dakotas, and other States, in place of the bonanza farms. It is better than bonanza farming, but it is a bad thing and ought to be circumvented. (934, 935.)

Mr. WEDDERBURN says a great many who have owned farms have become tenant farmers, and predicts that the Twelfth Census will show more tenant farmers in this country than ever before. (628.)

Mr. STEVENS cites the census of 1890 as showing that the farms in Georgia cultivated by the owners were about 46½ per cent of the whole, those rented for a money value 17½ per cent, and those rented for a share of the product 36½ per cent. (907.)

Mr. WHITE testifies that the farmers who own their land in North Carolina are, as a rule, more responsible and respectable than the tenants; though there are some very respectable men who do not undertake to buy land, but, taking into consideration taxes, purchase price, etc., prefer to share crops. (421.)

Mr. POOLE says that in the Black Belt of Alabama the lands are owned in large tracts of 320 to 2,000 acres generally, and frequently a man will work from 50 to 150 tenants on his place. (919.)

Mr. KYLE testifies that the tenant system is almost universal in Mississippi. A tenant can cultivate on an average 15 acres for each hand in the family who works in the fields. (467.)

Dr. STUBBS says Louisiana has two distinct classes of cotton planters: (1) Those located in the Mississippi bottom, from Baton Rouge to the Arkansas line, constituting the Jensas bottom, with an area of 4,000 or 5,000 square miles, and in the Red River bottom, running down from the northwest to below Alexandria, from 2 to 10 miles in width, "a most magnificent cotton section." In the alluvial bottom lands are large estates, many of them owned by absentees and worked by tenants. (2) Between these is "the hill country," consisting of land covered with oak and hickory and short-leaf pine. In these hills are a large number of small planters who grow cotton, corn, oats, and forage crops and raise small quantities of stock and poultry, make their own butter and meat, and live well, doing much of their own labor and hiring the help they need during the season. In the alluvial section the negro is a tenant; in the hills renting or sharing is the exception. (775.)

Mr. NORFLEET, of Memphis, testifies that the lands in the Yazoo Basin are largely operated by persons who rent land and, in some cases at least, subrent to other tenants. Some who have plenty of money and own as many as 50 mules still rent land. Some have paid as high as \$6,500 rent a year. Hill land in the Memphis district is worth from \$2 to \$4 an acre, cash rent, and arable lands of the Mississippi bottom from \$3 to \$6 an acre. (487, 488.)

Mr. HILL, of Memphis, Tenn, says most of the plantations in that vicinity are run on the tenant system. (504.)

Mr. PEEK says the South is rapidly going into industrial slavery, and the lands are all getting into the hands of a few men. According to the Eleventh Census, 65 per cent of the citizens of the country are homeless, and in Georgia 80 per cent are in that condition. We are a nation of tenants. Mr. Peek attributes this condition of things to the following causes: (1) The national banks can not loan money on real estate, and the State banks and loan associations loan only at ruinous interest; the Georgia banks charge from 8 to 12 per cent on real-estate loans; (2) the protective system is not carried far enough; all our agricultural exports are sold in competition with the products of pauper labor; (3) the State and Interstate Commerce commissions are helpless to enforce the laws. (462-464.)

Mr. NAFTZGER testifies that in central and northern California the Chinese and Japanese are tenants of a very considerable number of fruit orchards. They go especially into deciduous fruit growing and the making of dried fruit. They are not engaged to any extent in citrus fruit growing. (953, 954.)

2. Cash rentals and crop sharing.—*Northern States.*—Mr. POWERS says crop sharing is the old method of tenancy, as a rule, in the Northern States, and the most satisfactory method where the tenant has only a small capital. Where the tenant furnishes the implements and live stock he usually receives one-half the product. If the owner of the farm furnishes all the stock, implements, and seed, the tenant retains only one-third. There is now a tendency for tenants to assume the risk and pay a cash rental where their condition is improving. In sections where farm lands are valuable it takes a man of some capital to become a cash tenant, but the most desirable tenants are those who have capital. (172, 173.)

Professor DAVENPORT testifies that it is much more common than formerly in New England for landlords to stipulate that the tenants must manure the land. (263.)

Mr. SPEAR testifies that there is considerable renting of farms on shares in Vermont, though the fixed rental is on the increase. In share renting the landlord usually supplies the stock, tools, and machinery, and outside expenses, as for seed, fertilizers, and necessary repairs, are shared equally. The income is also divided equally. (403.)

Mr. STOCKWELL thinks there is very little crop sharing in Massachusetts, except in a small way. Sometimes a man makes an agreement with a farmer to raise a crop for him on shares, but this is infrequent. (886.)

Mr. NORRIS says that in New York a man rents a farm for so much, agreeing to do certain things. Farms are now being worked more extensively on shares than formerly. A man furnishes one-half the seed and does all the work, and the product is, as a rule, divided equally. In some cases where the owner furnishes the teams and all seeds, the tenant has one-third. When the man who does the work furnishes his own team, the owner, perhaps, pays a little more than one-half, under certain conditions, as where they run an evaporator. If a man evaporates the fruit, furnishes help, etc., the farmer generally pays him a little bonus. (322.)

Mr. COLES, of Salem County, N. J., testifies that there is a good deal of tenant farming on shares in that section. Generally, if the farmer owns the stock he farms for one-half the crop, finding half the seed, and generally half the commercial fertilizer. Where the owner of the land owns everything, and the tenant furnishes only the labor, he gets one-third of the crop. These terms have always been customary, but since there has been so much dairying and stock raising the owner of the farm is apt to have an interest in the stock also. (125.)

Mr. KETCHUM, of Mercer County, N. J., says the system of farming on shares is in vogue quite extensively in that section, on the usual terms of one-half or one-third, according to the ownership of the stock. (134.)

Mr. BRIGHAM, speaking with special reference to Ohio customs, says the owner sometimes furnishes all of the stock, tools, etc., in which case the tenant usually receives one-third. The owner and tenant sometimes each furnish half of the necessary supplies and then divide the product equally. In some sections the tenant is required to furnish almost everything. The division of the crop depends somewhat upon the fertility of the soil. In addition to his share of the crops the tenant is usually allowed a garden plot of his own and the use of fruit, and certain other privileges. (9, 10.)

Mr. SMITH, testifies that sugar beets were grown in Michigan almost exclusively by those who owned the land until 1900, when there appeared a tendency, especially at Holland and Benton Harbor, and somewhat at Bay City, to rent fields for cash rent to men who knew more about beet growing than the owners did and were willing to take chances. The renters were usually Germans or Hollanders. The factory at Holland also rented some land for 1900, and had to pay \$8 and \$12, and in some cases more, per acre. The renters take the land in small tracts, for the most part. One German rents 2 acres because he has only enough children to work that much; another man has 5 acres; a company has rented 103 acres at Benton Harbor. (577-579.)

Mr. WILSON, master of the Illinois State Grange, says that the landlord in Illinois furnishes nothing but the land and the buildings and receives from one-third to one-half the crop (probably two-fifths on an average), and cash for all grass lands. There are very few farm partnerships in Illinois except in stock. The landlord and tenant will each own half the stock, and the man will put his labor against the land and receive half the proceeds. As a rule the landlord pays the taxes on the real estate, but sometimes the tenant pays part of them. (245.)

Mr. MORAN testifies that farm tenants in western Minnesota usually receive half the product, the owner of the land furnishing the seed and usually paying half the actual money paid for thrashing. (710.)

Mr. PROM, a banker of Milton, N. Dak., says he owns and farms by tenants 7 quarter sections near town. He furnishes the seed and pays half the expenses of planting and thrashing, and receives half the grain. These are the general terms for crop sharing in North Dakota, except that the owner does not generally pay half the thrashing; the tenant does all the work and furnishes the thrashing machine and horses. A very small portion of the grain raising of North Dakota is done by crop sharing, however. The land is mainly owned by actual farmers who do the work themselves, except that during harvest there is some transient hired labor. Middle-aged men with families of children are preferred as tenants.

Mr. Prom says the tenant gets a certain part of the field for his exclusive use for garden stuff, potatoes, etc. The tenant furnishes his own fuel, paying \$4 a cord for poplar, or \$5.50 for oak. (787, 788, 793.)

Mr. BUDGE testifies that farm tenants in North Dakota have half the crop if the seed is furnished by the land owner, or two-thirds of the crop if they themselves furnish the seed and plow the land.

Southern States.—Mr. BARRETT, of Georgia, says a large part of the farm work in the South is done by tenants. Sometimes there is a money rent, which, in the section where the witness lives, ranges from \$1.25 to \$5 per acre. In other cases the tenant pays from 500 to 1,000 pounds of cotton for as much land as he can work with 1 mule, having a house, garden, and wood free. Another common method is known as "cropping." The owner furnishes the mule and its feed and a house for the tenant; the tenant furnishes the labor and feeds himself; fertilizer and other expenses are divided equally, and the owner and the tenant share equally the crop. In all these cases the law gives the owner a first lien on the crop for his rent. (46, 47.)

Mr. GRAHAM says there are sections of North Carolina where agriculture is carried on nearly altogether by croppers and renters. The cropper is a farmer whose landlord furnishes the land and utensils and pays for the fertilizers in proportion to his part of the crop. The cropper receives from one-third to one-half of the crop. The renter furnishes the stock. The landlord furnishes the house, firewood, and fully

an acre for garden purposes, and gets one-third or one-fourth, more or less, of the crop. (434.)

Mr. NUNNALLY testifies that the greater part of the farm work in the South is done on the share plan, the landowner furnishing the stock and feed for the same, all the farming implements, dwelling houses, garden plots, firewood, and one-half the fertilizer, the tenant furnishing the labor and food for the same, and the crop being equally divided. (455.)

Mr. AGER testifies that the renting of lands is practiced in some localities in Maryland. He knows one gentleman who furnishes everything, and gives the tenant one-third of what is sold off the place. In other localities, where land is better, the owner furnishes usually one-half the seed and gives the tenant one-half the crop. (105.)

Mr. WEDDERBURN, master of the Virginia State Grange, testifies that in the tobacco section of Virginia, south of the James and east of Petersburg, the general plan is for the landlord to furnish only land and house, advancing the tenant's living and charging him for it, and getting one-fourth of the proceeds of the crop as rent. In some places the landlord furnishes everything except the labor, and then gets about one-third. In the northern section of Virginia, near Washington, where land is valuable, the land alone is rented for from one-third to one-half the crop. Mr. Wedderburn thinks the only lien laws in Virginia are those applied on the advance of fertilizers. (620, 621.)

Mr. CLOHAN, of Martinsburg, W. Va., testifies that farming on shares in West Virginia is done generally by the whites, though one of the largest farmers in his section has a colored cropper, furnishing everything for him. Under the crop-sharing system in West Virginia the tenant furnishes everything and delivers two-fifths of the gross product to the landlord, the fodder and straw being retained on the farm. If the landlord furnishes teams and implements, the tenant gets one-third. Mr. Clohan estimates that one-half of the land in his locality is worked under the crop-sharing system. The landlords claim that their two-fifths gives them only about 3 per cent on the money invested. Quite a number of lawyers, bankers, and doctors own farms in that vicinity and reside in the city. (597, 598.)

Mr. NALL testifies that the system of crop sharing is growing in Kentucky, especially in the blue-grass region, because of the introduction within 15 or 20 years of the culture of Burley tobacco, which nearly all the blue-grass counties are more or less engaged in growing. The owners found that they did not know how to handle it with their colored labor, and induced white labor to come from the more hilly and poorer sections of the State as tenants. The landlord lets the tenant have whatever number of acres he wants, furnishes a house, pasturage for a cow and horse, a few acres for growing corn, and a garden, either with or without charge, according to contract. When the tobacco is sold at the warehouse and the expense is deducted, the tenant gets half and the farmer half. The tenant furnishes the team, or if the farmer furnishes it he is entitled to pay for it. (804, 805.)

Mr. Nall says that a good deal of corn land also is farmed by tenants, but in that case the tenant, as a rule, is not furnished a house. The tenant furnishes all the labor and cultivates the land for one-half the product. If the landlord advances supplies it becomes a lien on the crop. (805.)

Mr. WHITE testifies that tenants in North Carolina usually farm on shares. They rent the ground and furnish their own teams and supplies and give a third or a fourth of the crop as rent for the land. When the landlord furnishes the house, team, seeds, and implements, they divide equally. Men have often done well on these terms.

When the crop is gathered and ready for division it is divided into piles and the landlord takes his share. Sometimes the landlord gathers his share, taking, for example, every other row of corn; but the tenant generally gathers the crop. (420.)

Mr. White says the tenant sometimes gives so much cotton an acre, or, in lieu of cotton, so much money, but money rent is the exception. (420, 421.)

Mr. PEEK says the tenant system is the rule in Georgia. The land is rented for so much cotton, or the landlord furnishes everything except the labor and half the fertilizer and takes half the crop. (458.)

Mr. STEVENS says that where the tenant system of farming prevails in Georgia the average tenant is furnished with a home, water, fuel, pasturage for his stock, a share of the fruit on the place, a garden, an outhouse for stock, and storage for crops. In the sharing of the crop one-fourth of the cotton, one-third of the corn, and one-half of the small grain goes to the landlord, the balance to the tenant. The landlord furnishes the land and seed and a share of the fertilizer equivalent to his pro rata share of the crop. The lands are not let for continuous periods, but usually from year to year, and if the landlord becomes dissatisfied at the end of the year he can

dispense with the tenant, or the tenant may become dissatisfied and has a perfect right to go anywhere he chooses. The landlord has no lien and no claim upon the property or land except for rent and advances, which only apply to the present crop; moreover, the tenant is entitled to the benefit of the homestead exemptions, which are, to every man who is the head of a family, his household goods, his horse, \$300 worth of provisions, and so on. A tenant who has defaulted on one farm would not be regarded as a first-class tenant, but at the same time he can always get a place; some one will take him up.

Mr. Stevens finds it difficult to give all the reasons why so many of the tenants find themselves without any money at the end of the year, but attributes it in part to the exorbitant prices paid for goods bought on time, and partly to the ignorance and poor management of the tenants.

Growing crops are not attachable in Georgia, and if the tenant agrees to make the crop he does not have to stay the whole year, but can move at any time he chooses; there are no laws in the State to compel him to remain. (907, 908, 911.)

Mr. HAMMOND, a cotton planter of South Carolina, says that payment of rent in kind (one-fourth of the corn, one-fifth of the cotton), as was formerly the practice, is passing out of use. Money rents are generally paid at the rate of \$2 an acre for average land and more for the best quality. The system of crops on halves, the employer finding land, teams, implements, house, fuel, gardens, and half the fertilizers, is growing in favor. The cost of ginning, steam transportation to market, charges for insurance, and selling, are shared equally and are more than covered by the value of the seed. This system, as compared with that of hiring labor, gives additional security that the crop will be carefully gathered; and the cost of labor is 54 per cent of the cost of the cotton crop. When land is rented it deteriorates rapidly, but under the sharing system it is kept up. (822.)

Mr. DILLINGHAM says lands in Lowndes County, Ala., rent for from \$2 to \$3.50 an acre. The cash rent is growing in favor. The share system formerly existed to some extent, the landlord giving one-half the crop, or two-thirds if he furnished the machinery, but it has been largely superseded. (169.)

Mr. POOLE testifies that in Alabama the owner of the land furnishes the tenant house and all the necessary teams and implements. The tenant furnishes the labor and gets, generally, one-half the cattle and one-third of the corn and other crops. Frequently the landowner furnishes everything, including provisions, for, say, 6 months, and the tenant gets one-third of the crop. (918.)

Dr. SRUBBS says the negro tenants in the alluvial section of Louisiana are either sharers or renters: (1) If the landlord furnishes the house and mules, firewood, and feed for the mules, the negro will work the crop and feed himself, and divide equally at the end of the season. (2) The renter owns his mules and pays a stipulated rent, either in cotton, in money, or in cotton per acre. (775.)

Mr. KYLE, a lawyer of Sardis, Miss., has a place near Friar Point, in the Delta, which he rents for about \$4 an acre, money rent, to a white man, who subrents for a much larger amount to colored people and half a dozen families of Italians. These tenants run from one to four horse crops, cultivating about 20 to 25 acres in cotton to the horse. They generally raise their own meat and corn, and get supplies on credit from the chief tenant at the plantation store. Mr. Kyle also has lands in the hills where he supplies the labor himself. He does not hire by wages, but some of the colored people work on shares and some rent land. In working on shares the custom is for the landlord to furnish the mules or horses and implements, and the products are divided equally. No fertilizers are used except composts made on the farm. (464, 465.)

Mr. GAGE, a cotton factor of Memphis, testifies that his customers cultivate their land sometimes through croppers and sometimes by day labor. The share cropper is one who makes a bargain with the landlord to make a crop on shares. Generally the landlord puts up the land and a mule against the tenant's labor, and furnishes the tenant such supplies as he may want for his family during the year, charging him an agreed price for everything, generally a little higher than the cash price. The tenant, with his wife and children, makes the crop, and in the fall they divide the proceeds, or sometimes the crop itself. Nearly all the tenants are colored, but in the northern part of Arkansas a good many are white. (492.)

Mr. GODWIN testifies that he has a stock farm on the Wolf River, about 7 miles east of Memphis, and rents out his surplus land to tenants, who plant cotton mainly. A family cultivates from 25 to 50 acres, as a rule. A man who cultivates from 20 to 25 acres will have one plow animal; one who cultivates from 40 to 50 acres will have two. Mr. Godwin rents for cotton. For 20 to 25 acres of good land the rent is 2 bales of cotton; one tenant pays only 4 bales of cotton for 75 acres of good land. The tenants supply the implements and materials, but Mr. Godwin supplies

the house and all the firewood they want to cut. There are garden spots of from one-fourth to one-half an acre on which some of the tenants raise little crops of tobacco and potatoes and keep hogs, chickens, geese, and one or two cows. Mr. Godwin furnishes timber and nails for the paling around the garden, but the tenants very often burn it during the winter. (474-476.)

Mr. Godwin says that the law of Tennessee gives the landlord a lien upon the crops. Mr. Godwin does not keep a store, and prefers to have his tenants supply themselves elsewhere if they can, but otherwise he furnishes the absolute necessities, and by hiring his tenants to work on his stock farm he keeps their accounts very small. (475.)

Mr. Godwin says the tenants on his place come out even as a rule, and they made money on the crop of 1899. One of his tenants sold his last bale as late as March, 1900. (476.)

Mr. MASON, of Saulsbury, Tenn., besides hiring a few hands, rents two places to negroes, and has others working on shares, Mr. Manson furnishing the mules, feed, wagons, and implements and getting half the profit. He furnishes milch cows to his tenants without charge. (506.)

Mr. MASON, an ex-slave, testifies that he has been farming in Tennessee ever since emancipation. At first he rented 10 acres of land, with a house, etc., for a bale of cotton. He prospered, bought land, and now rents to tenants; the money rent averages \$2 to \$4 an acre. (498-500.)

Relative advantages of different plans.—Mr. DYE, of New Jersey, has found the system of cash rental more satisfactory than that of crop sharing. (84.)

Mr. M. F. GREELEY thinks there is not nearly enough crop sharing in South Dakota, and not nearly as much as there will be. He emphasizes the advantage of that method of farming to those who have large land interests that they can not oversee themselves. He thinks it is better, however, to give the one employed a little cash, crop or no crop, in order that he may feel sure of something. If he can also have part of the proceeds he is interested and does his very best. Mr. Greeley finds that he can let out a flock of sheep and give the man two-thirds and get more money out of it than by letting him have only one-half; when his self-interest is developed he becomes a better sheep man and a better farmer. (929.)

Mr. Godwin formerly practiced crop sharing and thinks it more profitable than renting for a stipulated amount of cotton, but a great deal more trouble. The landlord who rents on the share system undertakes the supervision of the tenants, who feel that they ought not to be interfered with, and the result is sometimes friction. When the land is rented the landlord only has to see that the tenants do not abuse the land and allow it to wash away. (475-479.)

Mr. ELDRIDGE, of Hillhouse, Miss., testifies that his son formerly made a great deal more money by working his plantation on shares and getting half the product than he now does renting the land for \$5 or \$6 an acre. (513.)

3. Advantages and disadvantages of tenant farming.—*Advantages from the standpoint of landowner and tenant.*—Mr. BRIGHAM predicts that crop sharing will be very largely employed in the future instead of money wages. A man will take more interest in work in the profits of which he is to share. (9.)

Dr. CROWELL says the English farmer is the most capable farmer in the world, because the business of land holding and land cultivation are separated; the farmer pays rent largely as interest on the capital the landlord has invested in buildings, drainage, etc., and has his capital free to use in cultivation. He is free to make the most out of the soil within certain recognized rules of cultivation, and his adaptiveness is marvelous. (340.)

Detrimental effects.—On the other hand, Dr. CROWELL refers to the disadvantage of the English farm tenant, under a lease prescribing a certain rotation of crops, in being obliged to sow a crop for which there may be little sale at the time, in contrast to the ability of the American farmer to adjust himself to changes. (333.)

Mr. BRIGHAM says that renting for cash ruins a farm. The tenant renting on shares will usually take good care of the farm. (9.)

Mr. POWERS considers the share system a detriment to the farming interests, especially where it is introduced with a view to making a permanent tenant class. He says that when a farm is leased to a stranger the land is apt to deteriorate; if it is leased to a relative or one who anticipates becoming the owner, the quality may be kept up. About 25 or 30 years ago there was a tendency on the part of rich farmers to buy up adjoining farms and lease them, but these farms were so generally deteriorating that they found it better to sell their land. (173.)

Mr. NUNNALLY, of Georgia, explains that the system of crop sharing had its origin in the lack of money with which to pay for labor. This ruinous system, he declares, has done more to impoverish the Southern farmers than any other combination of

circumstances. The labor thus employed works only about 7 months in the year, devoting the rest of the time to loafing, fishing, hunting, and having a good time. The contracts have grown looser and looser until the tenant ignores his landlord, and the tenants, as well as the landowners, have grown poorer year by year. The system may have been best at the time of its adoption, but on the whole it has been a stumbling-block in the way of progressive and diversified agriculture. (455.)

Mr. PEEK says there is a tendency with tenants in the South to get out of doing anything that keeps up the farm, such as terracing to prevent washing away of soil. (459.)

Mr. STEVENS, of Georgia, says the tenant system, as a whole, has a tendency to reduce the average production per acre of most of the crops, because a great deal is left to the management of the ignorant negro farm hand, the landlord being interested only to the extent of his rent. Public opinion is against the tenant system in Georgia for the reason that the crops and the land are neglected. The tenants go in to get what they can out of the land at the least possible expense, and pay no attention to building up the land or saving it; while the landowners who are native Georgians and live near by, permit this deterioration of the land without intervention as a matter of economy to themselves. They share in the extra present profits, and are recouped to a great extent for their losses by trading and trafficking with their tenants. A man continually in debt and wearing out the land under this tenant system is in a state of agricultural slavery, and it requires an abnormally large crop to get him out of debt. The tenants have no disposition to get out of the land anything but what is a present benefit. This applies not only to colored labor, but to white men as well. Mr. Stevens does not attribute the condition of the tenants to any oppressive disposition on the part of the landlords. (907-910.)

Mr. AGER thinks the tenant system undesirable for the owner; it is very difficult to get a tenant who has sufficient energy to work a farm as it should be worked. Owing to the cheapness of land in Maryland, a man with much ambition, energy, and industry is able to have land of his own. (105.)

Mr. DILLINGHAM, of Alabama, says on the authority of landowners who lease their land that the land is growing poorer. The people are also growing poorer. (166.)

Mr. HALE says there is too little of the owner's direct management in the case of rented land. He seems to be of the opinion that in the crop-sharing system, where the landlord furnishes the mule and bears part of the expense for fertilizers, there is tendency to stimulate somewhat better culture. (379.)

Mr. NORFLEET, of Memphis, says the tendency is to get rid of the management of the labor and rent land at so much an acre, furnishing cheap stock and utensils and improving as little as possible. He thinks this disposition to rent in this way is due chiefly to the desire of the negro to have charge of his own affairs without hindrance; on account of the scarcity of labor the landlords have to pursue the plan which suits the laborer best. As a result of this system the white people are, in thousands of instances, moving into the villages and towns. Under the management of the negroes the lands wash away and work out, and fences and other improvements become dilapidated. Mr. Norfleet thinks leaving the colored people together and alone so much also has a bad effect upon them morally. (486, 487.)

Mr. HILL, of Memphis, says the most serious objection to renting land is that it does not receive the same attention as it would under the care of the landlord. (504.)

Mr. JUMPER says that the land owned by mortgage companies in South Dakota and rented on shares reduces the average yield. The man who puts in a crop on another man's land never does it half as well as he cultivates his own land. (733.)

Tenancy a step toward ownership.—Mr. POWERS maintains that tenants represent, on the whole, an improvement upon the condition of farm laborers from which they have risen, though some of the negro farm tenants in the South represent a lower industrial level than the average farm-wage family of the North. Tenancy, except in isolated cases, is a step toward ownership. Many men accumulate enough money to retire from farming in their old age and surrender their farms to someone, often a son or other relative, or a hired man, who ultimately becomes the owner. As land rises in value it becomes necessary for young men to begin as tenants. The census of 1890 shows that the farm families whose heads were under 25 years of age were very largely tenants, while nine-tenths of those over 45 years of age were owners. It is becoming more and more common for young men to work as farm laborers; or they may start as tenants, and, if successful, buy the farm. (170, 173.)

Mr. BUDGE says the tenants in North Dakota work on shares only until they get a start, and then go out and take up land of their own. They generally become independent farmers, though they were practically all poor at the start. (846.)

Mr. CLOHAN testifies that the farm tenants of West Virginia prosper, and most of those who get on a good farm and stay 12 or 15 years ultimately become owners. (598.)

Mr. EDMONDSON, an ex-slave, testifies that he began renting on his own account in 1884 in Tennessee, and made 21 bales of cotton on about 26 acres of thin clover land, furnishing his own team and giving the landlord one-third. He made \$600 on rice and came out more than even. He has been able to save some money each year and expects to be able to buy a piece of land. (501, 502.)

4. Tenancy versus the wage system in the South.—*Impracticability of paying wages.*—Mr. GRAHAM says the man who attempts to farm under the wage system in North Carolina goes into bankruptcy because of the fluctuations in the price of cotton. (434.)

Mr. NUNNALLY, of Georgia, testifies that he works his farm entirely by the tenant plan; he can not get the labor to work otherwise. He has tried hiring men, but could not succeed while his neighbors worked on the other plan. Under the low price of cotton that was the only plan practicable. (455, 456.)

Mr. PEEK, also of Georgia, agrees with Mr. Nunnally that the system of tenant farming is the only one practicable in the South. The laborer wants liberty, and under the tenant system he has liberty to come and go as he pleases. (459.)

While condemning the tenant system severely, Mr. STEVENS says there is really no way to get rid of it; the landlord usually owns a great deal more land than he could cultivate himself, and there is a disposition on the part of colored laborers to become tenants rather than farm hands, because they are their own masters under the tenant system to a much greater extent; while the farm hands are required to work from Monday morning until Friday night, the tenant farmer is free to come and go as he chooses. The tenant farmer usually does work just as hard as the farm hand, but he is his own overseer, as well as his own workman, and for that reason his condition seems better to himself. The landlord does not rent the land so long as he can get better labor, but it is impossible to get just the labor he wants, and the result is that he is forced to resort to the tenant system of farming. (907-909.)

Mr. GODWIN, of Tennessee, says one can not afford to cultivate cotton with hired labor and sell it for 5 or 5½ cents. (479.)

Mr. MAXSON, of Tennessee, does not think he could raise cotton at the present prices (March, 1900) with hired help, unless he needed the help for other work about the place. (506.)

Mr. NALL, of Kentucky, considers crop sharing more satisfactory than hiring for tobacco raising. (805.)

Advantages of the wage system.—Mr. REDDING, of Georgia, tried to hire for wages from the time the negroes were made free, and is satisfied that that is the correct method. He thinks as a rule the farmers have been most successful who have hired by the month or year on a money basis. (44b.)

Mr. HALE says he could not make interest on the money invested in farms by letting them out to renters. He would prefer to hire the labor and have absolute control. He thinks a man with capital can go South, hire his labor, and by close attention to details make from 10 to 20 per cent in various lines. (390.)

Mr. HILL, of Memphis, has tried both systems and thinks that paying cash for labor and running the plantation is the more satisfactory. He raises grain, cattle, and hogs with wage hands. (504.)

Dr. STUBBS attributes the intelligent and economical cultivation prevailing in the lower portion of Louisiana to the exclusive employment of hired day labor on the estates under intelligent supervision. The negroes are taught to use improved implements and methods by the experienced and educated supervising overseer or manager, who remains with them all day, riding from one to another, pushing them, and seeing that the work is done properly. (770.)

Mr. LOVEJOY, of Georgia, believes that the laborers who get \$6 or \$8 a month are better off than those who rent or share crops. (75.)

D. Crop liens in the South.—1. *Origin and results of the system.*—Mr. HOLMES says it is a general custom of cotton planters and their tenants to use their credit with the neighboring merchants to obtain their plantation and family supplies in advance of the maturing of the crop, often even before the seed is planted. The farmer estimates about how much credit he wants, and the merchant tells him to produce so many acres of cotton, allowing a good margin against a possible crop failure. This system permits the planter and his tenants to live in the future, and to be improvident and hopeless. It is a direct cause of the enormous production of cotton, with a constant tendency toward overproduction, and of the low price of cotton. The cotton men are beginning to realize that they are the victims of a bad system. The store system of the South amounts to a sort of peonage with the cotton planter. The rate of interest on the liens of cotton crops averages at least 40 per cent a year, and the planters are at least a year behind. (160-162.)

Mr. HALE says the credit system of the South is a temptation to men without business experience or tact to tempt fate. Because the negro or the white farmer can get a loan on his cotton crop he is tempted to plant more than he otherwise would, and perhaps to buy more than he is able to pay for. Yet there are many who could not do much business if they could not get credit. Mr. Hale thinks the majority of Southern negro farmers who get advances on their crops get out of debt each year in October, or at least once in 2 or 3 years when they have an exceptionally good crop or prices are high; but they start in again in January, and are practically never out of debt. (380, 381.)

Mr. HAMMOND, a cotton planter of South Carolina, says that if the system of liens on the cotton crop were abolished, the amount planted would be materially reduced and the price increased. Cheap cotton is a vast advantage to the manufacturers and the world at large, but it is injurious to the yeomanry who provide it. (822, 827.)

Dr. STUBBS declares the crop-lien system a curse, though intended to be a blessing. After the war it was difficult to get money to farm with, and something had to be done; so almost every legislature in the South created a lien law to provide farmers with credit. It was asked for by the best people, but in the end was found to be detrimental, because even a white man, as soon as he gets credit, is very apt to go too far into debt and come to rely upon the merchant for supplies. (776.)

Mr. DILLINGHAM regards the crop-mortgage system as a step up from the condition of the negro at the time of his emancipation. It was the beginning of free contracting. (165.)

2. The merchant's risk.—Mr. LOVEJOY, himself a merchant, believes that the excessive rates of interest are one cause of the depressed condition of agriculture in the South, but justifies them in part by the high risks which are taken by merchants and money lenders. The merchant in making advances of goods to the planter, and especially to the laborers and negroes, adjusts the price of the goods to the credit of the individual. If a man is practically certain to pay, goods will be sold at perhaps 10 per cent advance of the cost; if the risk is high, the advance will be 25 per cent or more. The purchasers understand that these distinctions are made and the reason for them. Corn bought at 53 cents is sold at 60 cents for cash and at 75 cents on time, while bacon costing about 5.4 cents is sold for 6 cents in cash, or from 7½ to 10 cents on credit.

The merchant takes a lien on the crop for his advances, and of course runs considerable risk, since the crop may not turn out satisfactorily. The entire system, which has been in existence for 30 years or more, is bad for the merchants as well as for the planters. Merchants are not prosperous when the farmers are not, because they lose so much on their advances. Farmers do not borrow much money on crops and chattel security from banks, but chiefly from merchants, who themselves obtain loans from the banks. (75-78.)

3. Law and practice in various States.—*Kentucky.*—Mr. NALL quotes several sections of the Kentucky statutes, providing that a landlord shall have a superior lien without exemption upon the whole crop of the tenant raised upon the leased premises to reimburse him for money or property furnished the tenant to enable him to raise a crop, or to subsist while carrying out his contract of tenancy; also that when a tenant holds premises by virtue of a contract stipulating that he is to labor for the landlord, and fails to begin such labor, or without good cause fails to comply with his contract, his right to the premises shall at once cease. Mr. Nall says the law seems to be satisfactory to both parties. (805, 806.)

Loans by cotton factors in Tennessee.—Mr. GAGE, a cotton commission merchant of Memphis, testifies that in Tennessee rent is a statutory lien on the crop, and unless it is waived the landlord can get the proceeds of all crops, taking priority over anyone else the renter may be indebted to. Commission merchants, therefore, do not do business with renters to any extent unless the landlord waives his rent. Where they do business with renters they generally take a mortgage on the crop and live stock. (492.)

Mr. MOSELEY, of Memphis, does not believe that the farmers borrow much money from bankers; they get most of their money from the commission men who stand between them and the bankers. Anything over 6 per cent is usury in Tennessee. (516.)

Mr. NORFLEET, of Memphis, testifies that the cotton factors do not buy cotton at all, but they advance money and supplies to large farmers and planters. The colored people, as a rule, do not come to Memphis to get advances, but trade in their locality. It has been the custom for 50 years for the white farmers to come to the factor for money to make their crops. (488.)

Law of landlord and tenant in North Carolina.—Mr. GRAHAM, of North Carolina, says a landlord in that State has the first lien on the crop for his rent and supplies

furnished the tenant without any writing of any kind. Mr. Graham regards the verbal contracts now in effect as decidedly preferable to the written contracts formerly used, because more easily understood and remembered by ignorant tenants. (437, 438.)

Mr. WHITE, a colored member of Congress from North Carolina, testifies that since the war North Carolina has had a homestead exemption of \$1,000 worth of real estate and \$500 worth of personal property not liable to execution for debt on any judgment except on a mortgage given on that specific property. The law makes the furnishing of supplies and the rent of the landlord a lien upon the crop without any written agreement. The crop can be mortgaged even before it is planted. The removal of the crop without satisfying the lien is a criminal offense punishable by imprisonment; if the tenant removes a peck of potatoes without satisfying the landlord's claim for rent he is indictable. Sometimes the tenant lives on a little plot of ground of his own and rents land on the landlord's farm. When the landlord furnishes the house as well as the ground there is usually a little garden patch where he allows the tenant to grow the vegetables he may need on the table; but Mr. White has known cases where tenants have been indicted for gathering even out of the little garden spot.

Since the adoption of the homestead law the distinction between grand larceny and petit larceny is abolished, and all larceny is grand larceny. A great many men have been sent to the penitentiary for stealing a chicken worth 25 cents, but Mr. White has traveled as solicitor with one judge who refused to notice the stealing of a watermelon or chicken as too trivial a matter for a court to take up, and directed the solicitor in all such cases to enter a nolle prosequi. By a recent act the law has been modified so that if the article does not exceed \$20 in value the sentence for the first offense can not exceed 12 months' imprisonment. Larceny is a felony and the offender is disfranchised.

The application of the homestead act makes the records of the penal institutions very plethoric, and misleading to those not familiar with the facts. While the law was intended as a benefit to the poor man, Mr. White says that it works a real harm to him, because the landlords are almost forced to invoke criminal law to collect what otherwise they could collect by civil procedure. It is difficult for a tenant to avoid violating the letter of some law, and some landlords use that as a lever to hold the tenant, when he is disposed to go where he might better his condition by promising immunity from prosecution. Technical violations of the criminal law, however, are not invoked by the better element of landlords.

At the end of the crop year, in a great many instances, the tenant is unable to satisfy the lien and has to mortgage himself again. In a great many instances he is unable to get out of debt and goes from bad to worse. There is a great deal of fraud perpetrated on the ignorant who keep no books. In the fall the account is what the storekeeper chooses to make it, and the debtor can not dispute it because he has kept no account. (416-421.)

Mr. White says there are very few tenants who get cash on croppers' liens. If a tenant wants something at the store, he gives security and goes to the store and gets what he wants, and it is charged to the landlord. An act was recently passed prohibiting negotiations of the scrip. In some cases the stores charge a profit of 20 per cent. In many instances 50 per cent is charged. Mr. White considers the stores necessary, however. (433.)

Mr. White states that under the common law a tenant cultivating on shares taking part of the crop before the division would not be liable, because the crop is attached to the real estate, and real estate can not be stolen. (430.)

Mr. White suggests that the abolition of the homestead law would tend to better the condition of the negroes in North Carolina. He thinks the landlord and tenant should be put on an equal footing. Laws could be enacted that would protect the landlord while lessening the oppression of the tenants, but there is not a disposition to do so. (430.)

Advances by cotton factors in South Carolina.—Mr. HAMMOND, of South Carolina, says that the system of liens on growing crops is general. Small proprietors and renters get advances of \$10 a bale from the cotton factors, secured by lien or chattel mortgage. Mr. Hammond declares that the law for collecting liens on crops ought to be done away with. It has substituted an artificial credit for the proper and natural credit based on character and thrift. It has dismissed the intelligence of the community from the supervision of its industries, has led workmen into speculative undertakings that have brought them to bankruptcy, and has delivered them soul and body into the hands of the crossroads grocery dealers. "It is a legacy of the carpetbagger that has drained the country of the little he spared." Formerly the small farmer was not infrequently raided under the lien laws, but of recent years

the law is seldom resorted to; the victim, if there is one, has been trained to yield to the inevitable without resistance. (822, 839.)

Loans and advances to tenants in Georgia.—Mr. NUNNALLY, describing the tenancy system of Georgia, says loans are made to the tenant by the landlord or merchant in nine cases out of ten, and are secured by mortgage on the crops to be planted. Under the Georgia laws, in the absence of a contract the landlord is first paid out of the tenant's half interest for the supplies furnished. The law has worked well, giving protection to the landlord and food to the tenant. It is sometimes used to defraud other creditors, but only by men who are paid by the tenant to do so. (455.)

Mr. BARRETT says the law of Georgia gives the landlord a first lien on the crop, and the person furnishing supplies a second lien. Often the owner himself is forced to borrow or get advances of supplies, and has to waive his lien or discount the note of his tenant. The tenant who gets food and other supplies on credit is charged prices 50 to 100 per cent above cost. Liens are given on nine-tenths of the cotton raised. They fall due October 1 or 15, and in consequence practically the whole crop is forced into the market at the same time, depressing the price. Mr. Barrett thinks the law should not allow crop liens or mortgages. (47-49.)

Mr. HALE, of Georgia, says the owner of land always has a lien on the crop of his tenants for the rent. The landlord usually either buys the fertilizer or gives security for it, and there is also a lien on the crop for that, and generally for the year's supply of rations. A local store may furnish the rations and take a lien on the tenant's half of the crop.

Mr. Hale says the South is overrun with cheap goods of every kind, made for the Southern trade, and that something is needed to stimulate the use of better goods. He estimates the profits of the storekeepers at from 25 to 50 per cent. One great trouble, he says, is that there are too many small stores. Where there should not be more than two or three, there are a dozen general stores, and there is not enough business for all at a reasonable profit. (380.)

Mr. STEVENS says loans and advances to the tenants by the landlord are general in Georgia. The landlord must furnish supplies and mules with which to make the crop. If he prefers, he has his factor or merchant furnish these supplies to the tenant, to be paid for when the crop is marketed, the merchant frequently taking liens on the crop of the tenant to the extent of the advances. The effect of this is that the tenant frequently pays an exorbitant rate of interest. Credit prices are from 20 to 25 per cent higher than the cash prices, and while the legal rate of interest in Georgia is 7 per cent, and 8 per cent may be collected by special contract, it is considered perfectly legal to charge from 20 to 25 per cent more than the cash price for goods sold on time. (907, 912.)

Mr. Stevens does not see how the credit system, so far as the buying of supplies at "time prices" is concerned, can be controlled by legislation, but hopes the Industrial Commission will be able to recommend some way. (912.)

Mr. PEEK says a debtor can give a waiver on his homestead in Georgia. He thinks the homestead should be made secure. (463.)

Crop mortgages in Alabama.—Mr. POOLE says that negroes rent the land from the landlords in the 18 Black Belt counties of Alabama, and in 6 or 8 other agricultural counties. Generally there is an advance by merchants in the villages and towns, who take a mortgage on the growing crop for supplies furnished the laborer or tenant. Frequently the land owner makes an arrangement with the store for the supply of food to the tenants. The tenants pay a small percentage above the cash price, but extortionate profits are not charged, and as transportation has improved and competition has increased, provisions and other things have steadily grown cheaper. (919.)

It is customary in Alabama for the land owner and the tenant to sign a contract, usually on the 1st of January. Sometimes the tenant will run off and leave his crop, and in some rare instances he is prosecuted for the offense criminally, and if he has obtained money by false pretences, sent to jail; but his intention is very hard to establish; intent to defraud must be established in prosecuting criminally. Mr. Poole says that a negro has less regard for his contract than a white man, if he can better himself by going elsewhere. A recent law makes it a misdemeanor to break a contract without proper notice. (925.)

Dr. STUBBS says the crop-lien system is just as bad in Alabama as in Louisiana. (See CX, below.) (776.)

Plantation stores in Mississippi.—Mr. KYLE, of Mississippi, defines a plantation store as a store on the plantation, generally owned by the landlord, to furnish supplies to the people on the place. The statutes of Mississippi give the landlord a lien on all crops produced by the tenant, to secure him for rent and supplies. This gives the tenant credit at the landlord's store, which he would not have elsewhere, and his circumstances are such that he is almost compelled to deal there. Mr. Kyle does

CXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

There is a disposition on the part of banks to loan money to the farmers. They loan in the city of Griffin at 8 per cent, on personal securities and mortgages on the crop, land, and stock. (444.)

Mr. MOSELY says that anything over 6 per cent is usury in Tennessee. (516.)

3. **Southern banks.**—Mr. YOUNG does not think the county banks of South Carolina are making money, even at the high rates of interest they command. He speaks of one having gone out of business. They very soon loan their paid-up capital, then they get a certain line of securities and arrange with New York banks to borrow money at 6 per cent, to which they have to add their profit. They have their money tied up in real estate and can not now realize the amount of the mortgages. (119, 120.)

Mr. POOLE, of Alabama, testifies that there was only one bank in his county 25 years ago, and the farmers borrowed their money from commission merchants at Mobile and Selma, pledging their shipments of cotton. During the past decade 5 new banks have been started, and any farmer known to be a debt-paying man can get what money he needs at 8 per cent, the legal rate; frequently money is loaned for less. Mr. Poole has seen men pay 20 per cent. (926.)

Dr. STUBBS says the banks of Louisiana are all prosperous. In the small towns, including most of the county seats, there are State banks; but there are national banks in Shreveport, Monroe, and St. Charles, as well as New Orleans. Louisiana has a State inspector of banks, and maintains a pretty thorough control over them. Dr. Stubbs says the present national-bank law is based on the old Louisiana law to a great extent. New Orleans paper was perfectly good before the war, and the banks were widely known. The word "Dixie" originally meant the New Orleans \$10 notes, which were known throughout the Mississippi Valley and elsewhere. (776, 777.)

III. AGRICULTURAL LABOR.

A. Condition of farm laborers.—1. **General statements.**—Mr. BRIGHAM, Assistant Secretary of Agriculture and formerly a member of the Ohio State Board of Agriculture, says that where he is best acquainted the number of laborers regularly employed on farms by the month or year has remained about the same as in earlier periods, but the amount of transient labor has decreased, especially by the introduction of improved agricultural machinery. The modern practice in haying and harvesting is to shorten the duration of the work as much as possible, and it is found very difficult often to find sufficient transient labor at that time. Most of the farmers find work for their men the entire year round and prefer to keep the same men for years without change if they prove satisfactory. There is thus employment through the entire year for faithful men.

The condition of farm laborers is quite satisfactory, and much better than in earlier years. The wages have risen, the work is less severe on account of improved machinery, and since the fall in the prices of farm products the farm laborer is often better off than his employer. The laborer is on the same social plane with his employer in most cases, eats at the same table and has a good deal of freedom. The degree to which farm laborers save money and become independent farmers varies greatly according to their industry and economy. Usually an energetic man can become independent in course of time, although of late years many have considered it preferable to continue to work for wages. Farm laborers belong to the same organization with the farmers themselves. They have no separate organizations for their protection. (5-8.)

Several details of this testimony are confirmed by Mr. JONES, Master of the National Grange. (33.)

Mr. DYE, secretary of the New Jersey State Board of Agriculture, confirms, generally, the testimony of Mr. Brigham concerning the improving conditions of farm labor. The conditions in New Jersey, however, appear to differ slightly from those in Ohio. The growth of manufacturing, railway building, etc., has caused a decrease in the number of farm laborers, especially among the natives. To some extent improved machinery has decreased the demand for farm labor, but there is still, on the whole, an insufficiency. The farmers are compelled to seek laborers in the cities and towns, largely of foreign birth. Colored labor also comes from the South for work during the summer, and the witness believes that this movement should be encouraged. (82, 83.)

Mr. POWERS says the natural interaction of forces is such that the owners and tenants of farms increase in number, the number of laborers decreases, and their wages increase. There is a greater opportunity for men to rise in farming than ever before. The great mass of the unmarried farm laborers are young people, usually children of the men for whom they work. (178, 179.)

Mr. SPEAR, formerly secretary of the Vermont State Board of Agriculture, says there has been a gradual falling off in the number of persons employed on farms in Vermont during the past 50 years; with machinery fewer men are required. The conditions of the laborers are very much improved; their wages buy more of the necessities of life. Mr. Spear does not think the average farm help has improved in intelligence or efficiency. The sons of farmers probably do not hire out to their neighbors as much as 30 or 35 years ago, but there is still much more native than foreign help. (402.)

Mr. STOCKWELL says the transient labor employed on Massachusetts farms in the busy season comes mostly from the manufacturing villages. In busy times, like the haying season, they get better wages on the farms than in the factories. (885.)

Mr. NORRIS, master of the New York State Grange, testifies that the social and moral conditions of farm laborers is very much better than formerly, and that they have more privileges. A large majority of those in his section are better informed and financially better off than 25 or 30 years ago. There is no reason why an industrious and sober farm laborer should not make a nice living and do fully as well as his employer. (320, 321.)

Mr. KERICUM, of Mercer County, N. J., testifies that among the farm laborers in that county there are a few Italians and other foreigners, but the greater part of the labor that comes from out of the State is from southern and southwestern Virginia. Comparatively few native young men work as farm laborers. In the northern part of the county, especially where dairying is carried on, the same amount of labor is needed in the winter as in the summer. He thinks about three-fourths of the laborers are permanent the year round. (132.)

Mr. BARRETT says the amount of agricultural labor employed in Georgia is increasing, but its condition is worse than ever before. Labor is becoming more transient, shifting from one plantation to another. Whites and negroes do not work together. The hours of labor, where it is hired, average a little over 9 a day. Day laborers are probably employed less than half the time. (46.)

Mr. CLOHAN thinks that fully half the farm laborers in Berkeley County, W. Va., own their own homes, the land being very low in price along the Northern Mountain. There is also a belt of cheap pine land, so the men can get an acre for \$10 or \$15 and put up their houses. The farm laborers in that vicinity are practically all Americans. (592.)

Dr. STUBBS does not think the agricultural laborers of Louisiana have accumulated much property. He estimates that there is less owned per capita than at the beginning of the last decade. (770.)

2. *Race* (see also, III F, *Specialized agricultural labor*, p. cxxviii).—Mr. LOVEJOY estimates that about 25 per cent of the laborers working on farms in the Southern States are white. The white laborers who work for wages are hardly more energetic and satisfactory than the negroes. They are perhaps somewhat more able to learn the use of improved farm machinery, but improved machinery is very little employed anywhere. There is so little mechanical skill among the people that they do not know how to put together or repair such machines as reapers and binders. White children after leaving school drift away from the farm whenever they are able to do so. (79, 80.)

Maryland.—Mr. AGER testifies that the farm laborers of Maryland are nearly all colored. During the summer, when they can get employment almost anywhere, they can hardly ever be kept more than a month. The best labor in Prince George County flocks to the city, attracted by shorter hours and larger pay. They would rather come to the city and black boots than work on the farm. Farther away from the cities the labor is less migratory. (104, 106, 108.)

Mr. Ager testifies that as a general rule the colored farm laborers require close superintendence, and do not often become intelligent hands. The white help in the South is not much better than the colored. Mr. Ager has lived in Wisconsin, and found the labor of Germans, Danes, and Norwegians cheaper, though better paid, than that he gets in Maryland. (106.)

Mr. WHITNEY says the negro population is the principal but not the only laboring class in southern Maryland. It is not nearly so large as farther South. (878.)

Virginia.—Mr. WEIDENBURN, master of the Virginia State Grange, says the colored laborer is generally satisfactory, and he does not believe the people of Virginia, who are used to him, would be willing to exchange him for any other kind. They know he is lazy and will steal chickens and pick up anything that is lying around loose, but they do not have to pay him very high wages, and he is the best laborer they can get. (620.)

West Virginia.—Mr. CLOHAN estimates that one-fourth of the laborers in Berkeley County, W. Va., are colored. The older negroes are first-rate laborers, but the younger ones, especially if they have a mixture of white blood, are a very trifling

class of labor. The negroes as a rule are trustworthy, and are probably not as brutal with teams as some of the whites. The terms of employment are substantially the same as for the white day laborers, but a great many more negroes are hired by the day than by the month, because the farmers do not like to bother their families to arrange two tables, and so let the negroes board themselves as much as possible. (593, 594.)

Kentucky.—Mr. NALL testifies that 41.5 per cent of the laborers employed on farms in Kentucky are colored. He estimates that of the remainder about equal numbers are white laborers and owners of small farms, the latter class being found mostly in the mountain section, where very little labor is employed. He believes that about 60 per cent of the white laborers are Americans. The colored labor predominates in the western and northern parts of the State, but there is very little in the south-eastern part, except in the mining districts. (803, 806.)

Mr. Nall says the colored laborer is not quite as reliable as the white laborer. Sometimes one colored man is worth a dozen whites of the kind available, but the German laborers are worth more and get a little more wages than the average colored man. (815.)

South Carolina.—Mr. YOUMANS, of Fairfax, S. C., has a plantation of about 4,000 acres, of which he plants about 1,300 or 1,400 acres. Houses are scattered over the remainder of the plantation, and these are leased to colored tenants, who work the land surrounding them. He hires them for 6 months in the year, and pays them by the day. The plowmen and foremen are about the only ones he hires steadily by the month. The tenants are not expected to neglect their own crops to work for him, but they always want work, and their wives and children attend to their crops. Mr. Youmans says he has raised most of the labor on his plantation, and has no trouble with them. He sees no difference respecting them now as compared with the system of slavery. (121, 122.)

Mr. Youmans has between three and four hundred negroes on his plantation, and has no complaint to make of their efficiency or conduct. He says they are like large children; they have to be looked after, but they respond to kindness more than any other race. He prefers colored labor to white. The white man does not obey him any better, and generally puts him to more trouble and is harder to please. The white man is paid the same wages for the same work. (119-121.)

Mr. HAMMOND, a South Carolina cotton planter, says that colored labor constitutes as much as 75 per cent of the rural laboring population of his State, and that some 75 per cent of the colored laborers are engaged in agriculture. They are used almost exclusively in the gineries and oil mills, and to a large extent in railroading, as section hands, firemen, trainmen, etc. They run stationary engines, cotton gins, and oil mills. Some 50-odd letters, published about 1885 in the *Tradesmen's Journal of Chattanooga*, from rolling mills and similar manufacturing establishments, testified that in the majority of cases such employers preferred them to white laborers. (822, 823.)

Georgia.—Mr. PEEK estimates that about 75 per cent of the colored people of Georgia are employed on farms. (459.)

Mr. HALE, of Georgia and Connecticut, estimates that 90 per cent of the agricultural laborers in the South are negroes. He considers the negro laborer of the South the best agricultural laborer in America. The Yankee boys are perhaps a little smarter for some expert work, but in general Mr. Hale says he can accomplish more work for \$1 in Georgia than for \$3 in Connecticut, and gets as good results, so far as labor is concerned. The average daily wage on his farm in Georgia is about 65 cents, as against \$1.25 in Connecticut; the additional advantage is in the efficiency, honesty of purpose, and faithfulness of the negroes. They need more definite orders than the white laborers in the North; one can not leave as much to their judgment, but with a clear explanation they do not need to be followed up any more closely than the average white man. Mr. Hale's superintendent once left the place in the charge of negroes for 5 weeks, and found everything in perfect order on his return. Mr. Hale also finds the negroes very adaptable; they have learned budding, pruning, and spraying, even mixing the solution. He has men who have put in 2,500 buds a day. It is pretty good work for the most efficient men in Northern nurseries to put in 3,000 a day, and they want \$3 and \$4 for it. Mr. Hale's packing house was built by negroes. He declares that negro labor is the foundation of the prosperity of the South. (382-384.)

Mr. Hale uses white men as superintendents for the most part, though some negroes make efficient superintendents. His permanent superintendents and assistants are white, but have under them foremen of gangs who are negroes and are very efficient. To the whites and negroes who superintend the picking of fruit he pays \$1 a day. (377.)

Mr. Hale testifies that in general the negro laborers in his section of the country are very contented and permanent. Some of them move about from plantation to plantation, but Mr. Hale has men on his place who were there as slaves, and they were very much alarmed when a stranger bought the farm for fear they would have to move off. Mr. Hale let them raise cotton while gradually working them up to fruit culture. (379.)

Mr. STEVENS says both white and colored laborers, but generally the latter, are employed for farm service in Georgia. For dairy products, and in business requiring a high grade of intelligence, white labor is employed; but the negro, under the direction of the white landowner, is the best labor for the cotton fields. At least 95 per cent of the colored laborers were either born and raised in Georgia or have moved there from adjoining States. They are not subject to malarial diseases as are the whites, and they understand the manners and customs and methods of cultivation employed in the State. Mr. Stevens considers the colored farm labor the best that can be obtained for that part of the country. Nearly all the labor in the cotton factories and other manufacturing interests is white. The white and negro laborers do not like to be together. Colored labor naturally goes to agriculture, and is also employed in the oil mills and in the guano factories, where the work is not very pleasant and is disliked by the whites. Colored labor has not been tried in cotton manufacturing, except to do menial work about the factories. Labor is not plentiful in Georgia, and the cotton mills may be forced to try immigrant labor.

Mr. Stevens predicts that the question of labor will settle itself. The colored laborers will naturally drift to the farms and perhaps to warmer climes, the whites going into factories and transportation. The negro's wants are few. He must have a church, a schoolhouse, and, "by all means, his rum and tobacco." (912, 913.)

Mr. NUNNALLY testifies that the greater portion of the field labor in Georgia comes from the colored population; about 20 per cent are white. The contracts are made on the same basis with either race. (455.)

Mr. REDDING says the farm laborers of Georgia are almost entirely colored. They do not seem to have much ambition to acquire farms, as a rule. The negro is pretty well satisfied if he gets enough to eat and coarse clothes to wear. (448, 449.)

Mr. BROWN, of Georgia, testifies that colored hands are paid from \$6 to \$8 per month, and in addition are given 4 pounds of meat and a peck of meal (weekly?), a good house, and a patch of 2 acres of land, on which they can raise vegetables, etc., or a bale of cotton. The more a negro is paid the less efficient he becomes. Mr. Brown cites instances to show that where negroes earn enough in 3 or 4 days out of the week to support them the entire week they can not be kept at work continuously. Higher wages mean more money for drink and gambling. The farm laborers really are better off, with the various privileges which they are given, than colored laborers in the towns. (71, 72.)

Notwithstanding his opinions as to the incompetency of colored labor, Mr. Brown has recently undertaken the experiment of dispensing with white overseers, and has found that it works fairly well so far. He has explained his purpose to the negroes, and they understand that the overseers will be reestablished if it should prove necessary. (73.)

Alabama.—Mr. POOLE says that in many instances colored men fill places of responsibility on the large farms of Alabama. Mr. Poole has a negro superintendent on one of his three plantations. (923.)

Mississippi.—Mr. KYLE, of Mississippi, thinks people would generally rather hire colored men than white men as farm help. They make better servants. (471.)

Arkansas.—Mr. BALCH, of Arkansas, says the negro is the most reliable, docile, and faithful laborer the Southern farmer has ever had. It is necessary to have a few more of them than if they were white men who were trying to get ahead in the world, but the negro is the laborer for the cotton farm. He is adapted to the climate. Mr. Balch has hired young men from the North, and found that they did more work than the negroes for a few months, but not after the hot weather came on, about cotton-picking time. (497.)

Louisiana.—Dr. STUBBS, director of the Louisiana experiment stations, says the negroes who are remnants of antebellum days are in great demand in Louisiana; but among the younger generation there is an indisposition to be taught, and, never having been trained, the younger negroes are not as effective as the older ones. (770.)

New Jersey.—Mr. DYE says that in some parts of New Jersey a considerable number of negroes come up each season from the Southern States to work on the farms. This practice is advantageous both to the North and the South, and should be encouraged. The great difficulty in securing domestic help in the Northern States also shows the desirability of immigration of colored women to the North. (87.)

Mr. KIRCHUM, of Pennington, N. J., testifies that the lack of good white help in that section has led to the employment of negroes from Virginia since about 1892.

He considers them preferable to foreigners. The first year or two they return South about Christmas time, generally returning to the same neighborhood the next year. Very few of them are hired through an intelligence office. Many of them are employed for the following year when they go South in the fall. They make it a point to return by the 1st of April, which is the time for employing help. Those Mr. Ketchum has employed can read moderately well, and several of them can write legibly, their attainments in these respects comparing very favorably with those of the native colored people in New Jersey. Mr. Ketchum would not care to trust them with intricate machinery the first year they are in the field, but they can drive teams, and if nothing gets out of order they can run mowing machines. (133, 134.)

Other Northern States.—Mr. HAMILTON thinks not many negroes go into Pennsylvania during the crop season, except perhaps in the neighborhood of cities, where berries are grown extensively, and women and children are employed in gathering the crop. (351.)

Mr. STOCKWELL says there is a very small percentage of colored labor in Massachusetts, and it is mostly in cities. (887.)

Mr. WILSON testifies that there is very little colored farm labor in northern and central Illinois, but a good deal in southern Illinois. As a class the negroes are not as efficient as white labor. (246.)

California.—Mr. SAYLOR says that in California nearly all the hand labor in connection with sugar beets, and nearly all vegetable raising, gardening, and that sort of work, is done by the Chinese and Japanese. (590.)

3. Social status.—Mr. HANLEY testifies that farm hands in Minnesota are admitted to the family as equals, eat at the same table, and partake of the same social conditions as members of the family. (275.)

Mr. POWERS says the average farm hand in the Northwest lives with the family of his employer and boards at the same table. In the case of a married man a house and garden is furnished free as a rule, if he works by the year or the month. (174.)

Mr. HAMILTON testifies that the farm laborer in Pennsylvania takes his seat at the table with the family as a rule. (351.)

Mr. CLOHAN, of West Virginia, says there are very few cases in his locality in which the white farm laborer who works by the month or the day does not eat at the same table with his employer. No such thing is allowed with the colored laborers. (594.)

4. Conjugal condition.—Mr. STOCKWELL, of Massachusetts, says many farmers prefer single men, and board them so as to have them right at hand. This appears to be the general preference. (886.)

Mr. BRIGHAM says many farmers prefer to hire married men to do their work. They furnish them with tenement houses, which are usually quite comfortable; they furnish also a garden plot, keeping no account of the vegetables raised. Fruit, also, is often furnished free, and the employee is allowed to keep a cow or a horse, or both. (9.)

Mr. DYE says tenant houses are falling down in many localities of New Jersey for lack of use, since laborers are more migratory and fewer of them married. (83, 84.)

Professor DAVENPORT, of Illinois, remarks a tendency to employ older men than formerly as agricultural laborers. His experience is that more married men are employed than 20 or 25 years ago, though the bulk of the laborers are still young men. The wife of an agricultural laborer often helps with the housework. The married laborer is generally employed for a year, by the month, and has a house with a little patch of land. Most of the married farm laborers in Illinois and Michigan, so far as Professor Davenport has observed, are American born. (255.)

Mr. POWERS says the number of married men among farm laborers is relatively diminishing. (174.)

Mr. GREELEY, of South Dakota, thinks the solution of the hired-help problem in that section is to encourage the tenant hired man with a wife and children. A single man may change at almost any time, and can not be depended upon nearly so well as one who is married, especially if he has a family; he then stays willingly the year round. If he has children they have the opportunity of growing up in the country, and his family are valuable help in busy times; it is much more convenient to employ them than to go after other help and perhaps pay very high for it. Again, the farmer does not have to pay all cash. He can give his tenant help a good garden and the use of one cow without feeling it much, and this means a great deal to a man with a family. If he can be provided with vegetables also, he can almost live on what the farmer can give him from the ordinary Western farm without missing it. The laborer who has a small piece of land to cultivate is learning how to get a living out of the land, and can lay up more money than one employed in the city at much higher wages. (928.)

5. Ambitions and prospects.—Professor DAVENPORT has noticed a decided change in the ambition of the farm laborer. Twenty-five years ago or more a man worked on

the farm for the sake of getting money with which to buy a farm for himself, but now that cheap lands are not to be had, there seems to be a decided tendency for the farm laborer to work without a very definite object and to use his money for whatever his fancy dictates, most likely a horse and buggy. (256.)

Mr. WILSON estimates that 50 per cent of the farm laborers of Illinois look forward to renting farms of their own. (244.)

Mr. GREELEY, secretary of the Board of Regents of Education of South Dakota, worked for 5 years on farms as a hired man before getting a small piece of land of his own. (929.)

Mr. CLOHAN says that in rare and exceptional cases the farm laborers in his neighborhood, besides raising their vegetables, kill a few good hogs; but that class of laborers in a very few years become tenant farmers. (593.)

B. Supply and demand.—1. Number of laborers.—*New York.*—Mr. NORRIS, of Sodus, N. Y., thinks the number of agricultural laborers in New York State has increased somewhat during the last 20 years, and that there is still (1899) a tendency toward increase. He thinks there has been an increase in the amount of transient labor employed in New York, especially in his section, owing to the harvesting of the fruit crops, notwithstanding the fact that the general harvest work is now done largely by machinery. (320.)

Illinois.—Mr. WILSON, master of the Illinois State Grange, thinks about the same number of agricultural laborers are employed in Illinois as 20 years ago, but the hired help is now very largely of foreign birth, whereas 20 years ago many were native born. Through central Illinois they are usually German, Danish, and Swedish. (243, 245.)

Kentucky.—Mr. NALL, Commissioner of Agriculture of Kentucky, says the population and farm acreage of Kentucky have increased, and the number of agricultural laborers has increased in proportion. They are very largely colored. (802.)

Louisiana.—Dr. STUBBS testifies that during the last decade of the century Louisiana increased the area cultivated and amount produced, and there has been a natural increase in the number engaged in agricultural labor, but not all of the natural increase has remained; he supposes there has been a comparative decrease in numbers. (769.)

2. Duration of employment.—Mr. SHEAR says some farm laborers in Vermont are employed through the year and the rest for 7 or 8 months, making an average of about 10 months. (402.)

Mr. STOCKWELL says that agricultural laborers in Massachusetts are hired by the month for 8 or 12 months. If a man is a good worker he usually finds work at all seasons. (885.)

Mr. NORRIS, of Sodus, N. Y., estimates the average number of days farm laborers are employed in the year in his section of the State at from 190 to 200. They are regularly employed 8 or 9 months of the year as a rule, and the majority of those who wish to can find work nearly the whole year at fair prices; but there are some of those who hire out for 8 or 9 months who are inclined to take things easy and have a good time after their time is up. (320.)

Mr. DYE says there is considerable irregularity of employment in New Jersey, owing to the fact that most farmers do not require much help during the fall and winter. Moreover, the laborers themselves are inclined to migrate, desiring to see new places and to try new employers. (83.)

Mr. WILSON, of Illinois, says more hands are employed by the year than 20 years ago, but the hiring is largely for 9 or 10 months. Many of the hands stay through the winter, feeding the stock or something of that kind for their board. They do not usually have to pay board in the winter. He estimates that the average farm laborer has from 250 to 300 days' employment in the year. They are hired by the month almost entirely, but are sometimes hired for a year at so much a month. (244.)

Mr. M. F. GREELEY says the farmers of Minnesota and the Dakotas generally hire men for about 6 to 8 months—more often 6 than 8. The bulk of the laborers, however, are hired by the day or for short terms during harvest, haying, and other busy times. (928.)

Mr. BUDGE testifies that the harvest labor of North Dakota is a floating population that comes in on the railroads and stays during the harvest, which lasts about 3 months. On some of the big farms there are a few hired men. A man who has 320 acres generally takes care of the farm himself, with his family, until spring; he then hires 1 man until harvest and has 2 or 3 during a harvest and thrashing. (846.)

Mr. PROM, of Milton, N. Dak., says no farm labor is done in that section during January, February, and March. The labor begins in April and is continued until November, when the hauling of grain begins. During the winter months the laborers generally stay on the farms, however, except those from Canada, who go home and visit relatives. (788.)

CXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. AGER, of Maryland, testifies that in dairying the laborers are employed 365 days in the year, but in other agricultural occupations there is not as much employment in the winter as during the growing season. (104.)

Mr. CLOHAN, of Martinsburg, W. Va., says farm hands in that vicinity are generally hired for about 9 months, from the 1st of April until the 1st of January. The better class of day laborers even get almost constant employment, except on rainy days. (592.)

Mr. NALL testifies that farm laborers in Kentucky can get regular employment. They usually hire by the year, wages being payable monthly. Soon after the war there was more paying by the year. (803.)

In reply to inquiries, Mr. Nall finds the number of days of employment in Kentucky to be stated at from 240 to 300 days. There is usually something for everyone to work at in Kentucky. (803, 804.)

Mr. HAMMOND, of South Carolina, declares that a good negro laborer finds employment and will work the year through, except holidays for funerals and society meetings and a few days at Christmas. The average laborer works from 200 to 250 days a year. There is a deep-rooted desire to have Saturday free. On that day the negroes collect in crowds in town or at the store. (819, 820.)

Mr. NUNNALLY, of Georgia, testifies that in the yearly contract with laborers it is often necessary to allow them two months in the summer for loafing, like those who are tenants. They can not be employed for the whole year. (455.)

Dr. STUBBS says the agricultural laborers of Louisiana are employed as many days in the year as they want to work, and a good many make 300 workdays a year. Dr. Stubbs has paid some for more than 300 days' work in a year. The average hand in the sugar district will work more than 200 days. In the extreme winter, after the crop is taken off, the plantation has no immediate use for all its hands, and may lay off some part of them during the rainy season of the winter, but some work the entire year. (775.)

Dr. Stubbs says it does not take nearly as many men to run a rice plantation as a sugar plantation. The rice planter needs men to break the land, but keeping the crop between planting and harvest requires only about one man to 300 or 400 acres, while the sugar planter requires a large number at all times. (777.)

Mr. NAFTZGER says the labor conditions in California are peculiar. There is practically no season when either fruit harvesting or grain harvesting is not going on. (953.)

3. Causes of irregularity of employment.—Mr. STOCKWELL says the wide-awake farmer will hire all the help he can with profit, and no more. He will discharge help he does not need. His demand for help is regulated by his expectation of profitable returns. He will adapt himself to the conditions of the season and the markets. (885.)

Mr. HANLEY says irregularity of employment is often caused by industrial depressions, which are often brought about by people living beyond their incomes. Under these conditions the farmer and his family try to get along with less help and do more of the work themselves. (274.)

Mr. POWERS says the greatest irregularity of employment in the North, particularly in the Northwest, is found where farmers raise one or two staple crops, to the neglect of diversified agriculture. There was more irregularity in the early days of the West than to-day, because the great central States of the North are tending naturally and inevitably toward a diversity of crops, which keeps the men engaged for a larger part of the year. Wherever a system of diversified farming is being developed the average number of days employed in the year is steadily increasing and transient labor is decreasing. (172.)

Mr. HALE says the irregularity of employment in the South is due to too little diversity of agriculture. Cotton makes a short season of a certain number of months, and the rest of the year there is very little to do. From 150 to 175 days is about the length of employment on the cotton plantation, but on fruit and truck farms there is employment for 12 months, except when the hands want a little vacation at Christmas. The fruit harvest, in June, July, and August, is a dull season with cotton planters. (376.)

4. Inefficiency of farm labor.—Mr. COLES testifies that the agricultural labor throughout southern New Jersey is not as good as a few years ago, because manufacturing establishments have taken the best help. In parts of Salem County the farmers depend largely on Southern laborers, who come North in the spring, many of them going back in the fall. There is a considerable colored population in the county, but it can not be relied upon as well as the newcomers from the South. It is sometimes a little difficult to keep the help as long as is desired. Though the men are trustworthy, they have been brought up to slow habits. (124.)

Mr. HAMILTON thinks the effect of manufacturing establishments is to take the best laborers, so that farmers now have to do with a less efficient grade of labor than 30 or 40 years ago. There is not now the same difference in the wages of harvest hands that there used to be before the introduction of modern machinery. (350.)

Mr. M. F. GREELEY, of South Dakota, says the average hired men in Minnesota and the Dakotas are not quite as good men as they used to be. They are determined to work fewer hours, though they are paid better wages than formerly. (927.)

Mr. WHITNEY says he can not see how thrifty methods can be introduced into certain areas. He does not think that any kind of education would improve the farming conditions in southern Maryland and make them attractive to young men. It would be discouraging for a young man to go back and live under the social conditions prevailing there; he can not do the work with his own hands, and does not have intelligent or efficient labor to carry out his ideas. The conditions are almost hopeless for the introduction of new methods and new crops on an adequate scale. (878.)

5. *Scarcity of farm labor.*—Dr. CROWELL says the British dairymen had to resort to milking machines because they could not get laborers to milk their cows. (340.)

Mr. ROGERS, president of the Binghamton Beet Sugar Company, says one of the troubles experienced by many farmers growing large areas of sugar beets is the difficulty of getting help for a few weeks in the busy season. (554.)

Mr. MILLER says the farmer does not use as much hired help as in former years, but there is a demand for help in the rural districts of Ohio. (617.)

Professor DAVENPORT says there is difficulty in securing good farm laborers in Illinois. The demand is perhaps for a better class of men than formerly, new machinery making the labor more complicated. (256.)

Mr. WILSON says the opportunities for getting transient labor in Illinois in busy seasons are poor; the labor is not to be had. The farmers get what men they can from the towns and villages. Mr. Wilson has never yet known the time when a good hand could not get work on a farm. (244, 246.)

Mr. HANLEY testifies that the farmers of Minnesota and the Dakotas have the greatest difficulty at harvest time in getting enough farm laborers to save the crop, although they pay from \$2 to \$3 a day. One thing which diverts laborers from the farms is railroad building, which affords regular work with shorter hours. (275.)

Mr. BUDGE testifies that help was scarce in North Dakota in 1900. There was a poor crop. The year before that there was more labor than the farmers could take care of. The railroads move the laborers to parts of the country where there is a good crop and a big demand for labor. (846.)

As explaining the scarcity of farm labor, Mr. NORFLEET estimates that there are 150 colored men at work as common laborers on levees and other public works within 3 or 4 miles of his plantation in Tunica County, Miss. They are paid from \$1.25 to \$1.50 a day. There is more or less of that kind of work going on throughout the entire section. (487.)

Mr. HALE says there is generally an abundance of labor in Georgia for everyone who wants it. He has had no difficulty either in getting negroes for field work or intelligent white people for picking and packing fruit. They come in far greater numbers than he can use. (376.)

Mr. HAMMOND, of South Carolina, testifies that serious losses are often caused by the irregularity of the laborers, though this is perhaps less true of the negroes than of any other agricultural laborers. (See also Negroes, p. —.) Farmers who live in the vicinity of the towns are considered fortunate in that they can draw on the town supply of day labor without being at the trouble and expense of maintaining it. Elsewhere expensive methods have been adopted to insure a supply. Farmers build numerous houses on their land for day laborers, so that if one fails another may be secured. They allow the laborers gardens, firewood, etc. Another plan is to keep a commissary and furnish supplies on credit. Although the profits charged in the commissaries are high, and although the negro laborer very seldom shirks or repudiates his debts, it is doubtful if the net gain amounts to much, because the employers often have to take payment in work that they would not have paid cash for. (819.)

Mr. STEVENS states that during the busy seasons the farmers of Georgia often find trouble to secure the necessary labor, and very often hire hands from the towns and cities. (906.)

Mr. GODWIN, of Tennessee, says he has no white labor, except one general superintendent and one to look after the dairy business. He has tried for a year and a half without success to get a white man to take charge of and assist in the milking, though he offered \$30 a month and a free house and fuel. He says that the class of white men that offer for hire in his neighborhood, as a rule, are "a very sorry class of men." (476-477.)

Mr. NAFTZGER testifies that until recently there has been an ample supply of labor in California, made up to a considerable extent of Chinese and Japanese, who are employed in agricultural pursuits of every kind; but more recently there has been a shortage of labor. The class usually found to do odd jobs is not fond of more work than is necessary. (953, 954.)

6. Employment agencies. (See also, as regards Chinese labor bureaus, III F 1, Naftzger, p. CXXVIII.)—Mr. POWERS testifies that during the last few years bureaus of intelligence have been organized in Western cities and men sent out to the farms as laborers. Every man out of work and ready to adapt himself to anything could thus find a place. Mr. Powers says it is wise in times of depression to find out where there is a deficiency of labor and send men there. (184.)

Mr. SPEAR says the farmers of Vermont secure immigrants as laborers through the immigration bureaus at Boston, New York, and other ports. (403.)

C. Hours of labor.—Mr. BRIGHAM says the hours of farm labor have been greatly reduced during the last 40 or 50 years. It was often the custom earlier to work from 5 in the morning until dark. At present 10 hours a day are considered good time; usually from about 7 until 6, with an hour at noon. In the winter the hours of work are 8 or 9. In the South hours are somewhat longer than in the North. Farmers generally feel that as much can be accomplished in 10 hours as in the longer period on account of the greater vigor of the work. (5, 6.)

Vermont.—Mr. SPEAR says the hours of labor on Vermont farms average about 10 a day; on dairy farms, probably 12 a day. (402.)

Massachusetts.—Mr. STOCKWELL says the legal day in Massachusetts is 10 hours, and it is very carefully and generally observed, though the hours vary in certain cases, as on milk and vegetable farms, where laborers are hired with the understanding that they will be paid in accordance with the length of the day. While 10 hours make a day's work, the early feeding and the later chores make the day longer; e. g., chores from 6 to 7, an hour for breakfast, and work from 8 to 12 count as 5 hours' work, but the hours are different from those of a man working in a mill, who begins and finishes his work without reference to the care of stock. (885.)

New York.—Mr. NORRIS, of Sodus, N. Y., says 10 hours is the established rule as to hours of labor on most farms in that section. (320.)

New Jersey.—Mr. COLES, of New Jersey, says the hours of farm labor have a tendency to grow shorter, as in other pursuits. (125.)

Mr. DYE says the hours of labor have been reduced in New Jersey, partly through the influence of reduced hours in manufacturing business. Men scarcely average 10 hours of actual work each day. They insist also on working continuously during the middle of the day, whereas it would often be more advantageous to the farmer to have them begin early and work late, with an intermission during the middle of the day. A still greater advantage might come from working two sets of men during the harvest season, so as to cover all the hours of daylight. Men are often careless of the interests of their employers in stopping immediately when hours are ended, to the injury of the crops. (83, 84.)

Mr. KETCHUM says the general tendency is to shorten the hours of agricultural labor, though truckers have to work long hours at certain seasons, and dairymen have to get around very early in the morning. (136.)

Mr. MAGIE says the hours of work for farm laborers are shorter than formerly in New Jersey, even in the dairy business, where the hours are necessarily long. In dairying, the hours are from 4 o'clock in the morning until about 6 in the evening, or longer in some seasons. (105.)

Illinois.—Mr. WILSON testifies that the hours of labor on Illinois farms have been shortened to about 9 hours in the field. The prevailing hours in central Illinois are from 7 to 11.30 and from 1 to 6.30. The farmers have conceded shorter hours for their own benefit; they wanted time for other things, and with improved machinery the longer hours were not necessary. Mr. Wilson thinks 9 hours long enough both for a man and for a team. (244.)

Minnesota.—Mr. HANLEY thinks the average hours of labor in harvest and thrashing time in Minnesota are from sunrise to sunset; some work until the moon rises. After the rush is over the farmers are very reasonable, and the hours are from 7 until 6, or even less. (275.)

North Dakota.—Mr. PROM testifies that the hours of labor on the farms of North Dakota are generally from sunrise to sunset. The season is so short it is necessary to use the whole day. (788.)

Mr. BUDGE, of Grand Forks, N. Dak., says: "During harvest we commence as soon as we can get out and work until sundown." At other times the hours do not exceed 10 a day. In the winter there is not much to do but to take care of the stock. (846.)

South Dakota.—Mr. M. F. GREELEY says the men seem to expect to work about 10 hours a day, though there are seasons, at haying, thrashing, etc., when they have to work longer. (928.)

Maryland.—Mr. AGER, of Maryland, testifies that the hours of labor in the dairy-ing business are generally from 4 or 5 o'clock in the morning to 7 or 8 at night, and about the same in other agricultural pursuits. He once heard a public speaker say that the farmers had settled the 8-hour question by having 8 hours before dinner and 8 after. (104.)

West Virginia.—Mr. CLOHAN, of Martinsburg, W. Va., says the hours of labor in his locality are from daylight to dark. (592.)

Georgia.—Mr. NUNNALLY testifies that the length of a day's work in Georgia is from sunup to sundown, with from an hour to an hour and a half nooning. Under the tenant system the tenants work about as they please. (456.)

Mr. STEVENS says the hours of labor on Georgia farms are from sunup to sundown, with 2 hours in the middle of the day for dinner and rest. Work continues from Monday morning until Friday night, sometimes until Saturday noon, Saturday being considered a holiday among the farmers of Georgia. The negro farm hand works on the average from 180 to 200 days, the rest of the time being spent in going on excursions, picnics, etc. (906.)

Louisiana.—Dr. STUBBS says the agricultural laborers throughout Louisiana work from sunrise to sunset. (775.)

The South generally.—Mr. HALE thinks the hours of labor are too long in the South; from 8½ to 9 hours in the shortest days and from 12 to 14 hours in the longest days of the year, certainly an average of 11 hours a day of field work. (376.)

D. Compensation (see also *Specialized agricultural labor*, III, F, p. cxxviii).

1. The increase of farm wages.—Mr. MILLER, secretary of the Ohio State Board of Agriculture, testifies that farm wages have greatly increased as compared with 40 years ago, but perhaps not as compared with 30 years ago. (617.)

Mr. HOLMES says the wage rates of farm labor have on the whole been increasing. The average wages of agricultural laborers in the United States in 1895 were \$17.69 per month, without board, a decline of \$1.49 from the average of 1893, when farm wages were higher than at any time since 1869. The average wage, without board, in the Eastern States in 1895 was \$29; in the Middle States, \$23.80; in the Southern States, \$12.71; in the Mountain States, \$30.04; in the Pacific States, \$31.68. (152, 157.)

Professor DAVENPORT says farmers pay as high money wages as they ever did, and the purchasing power of the money is vastly greater than 20 or 25 years ago for everything but land. Although farm wages are higher (1899) than 25 years ago, the farm laborer can not secure as much land or opportunity as formerly. (257, 267.)

Professor Davenport says the farmers feel that they are paying as much for labor as they can afford, and that, considering the cost of board, they pay as good wages as other employers. Professor Davenport thinks labor of the same grade is as well paid on the land as in most other lines, and that the surroundings are helpful and healthful. (257.)

2. Wages in particular localities.—*New England.*—Mr. BACHELDER, testifying early in 1899, says that the condition of farm labor in New England is better than ever before. Most laborers are employed by the year, and the wage is about \$25 a month. (42.)

Mr. SPEAR testifies that the maximum farm wages in Vermont are about \$275 a year, with board and washing. He estimates the minimum for fairly competent labor at \$150, but says that some are not able to earn much besides their board. Labor is usually paid for in cash as the money is needed, and a final settlement is made at the expiration of the contract period. There is usually a contract for a specific time. But few farmers provide tenant houses; where they are supplied the rent is usually reckoned at from \$2 to \$4 a month. (402, 403.)

Mr. STOCKWELL gives the following as the wages of agricultural laborers in Massachusetts: Wages by the month with board, \$16 to \$25; without board, \$28 to \$35, or higher in some few cases. Wages by the day, \$1.50 to \$1.75. Payments are nearly always made in cash, usually once a month. An employee may draw on account and perhaps leave a little balance in the farmer's hands to accrue during the season, but monthly payments are preferred by the employees. They can have them more often if they desire. (885.)

New York.—Mr. NORRIS, of Sodus, N. Y., says the usual farm wages in that section are \$17 or \$18 a month. The wages for single men include board and lodging, but not washing. The universal daily wage is \$1, and the man boards himself. The single men are all paid in cash.

Mr. Norris says the most progressive farmers in his section now pay their hands

CXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

every month, often hiring them at so much a day. Some continue the old practice of hiring for 8 or 9 months and settling up at the end of that time. (321.)

New Jersey.—Mr. DYK says the wages and general conditions of farm laborers in New Jersey are better than they were 40 years ago. Where men board themselves, wages are \$25 to \$30 a month, with a house and garden usually furnished; where they are boarded, \$12 to \$18 per month. Day wages are ordinarily from 75 cents to \$1, but during harvest time \$2 to \$2.50. (84.)

Mr. COLLES, of Woodstown, N. J., says the maximum wage for farm laborers in that section is \$20 a month and board. Not very many get that much. Wages range from \$20 down to \$12 or \$10 for hands employed through intelligence offices. Truck farmers pay somewhat higher wages than others, the season being short and the work exacting as to hours. Wages are paid in cash, by the month. (125.)

Mr. KETCHUM, of Pennington, N. J., testifies that the prevailing wages for farm labor in that section are from \$10 to \$20 a month and board. (133.)

Mr. MAGIE, a dairyman and stock raiser of Elizabeth, N. J., says that competent farm laborers receive more in his vicinity than they did 30, 40, or 50 years ago. In dairying the wages are from \$12 to \$20 a month and board, or \$30 or \$35 a month and house rent, for competent men. (102.)

Pennsylvania.—Mr. HAMILTON submits the following table of farm wages in Pennsylvania for 1899:

	Maximum.	Minimum.	Aver. ge.
Farm wages, by the month, with board (whole year)	\$20.00	\$8.50	\$12.69
By the month (summer only).....	25.00	10.50	15.83
By the day, with regular work (with board).....	1.00	.50	.80
By the day, with regular work (without board).....	1.40	.75	1.11
By the month, whole year (without board).....	35.00	10.00	20.07
By the month, without board (summer months).....	40.00	11.66	23.95
By the day, with board, for transient work (when wanted, only).....	1.63	.50	1.05
Harvest wages, by the day (with board).....	2.00	.90	1.29
Household help, with board (by the week).....	3.00	1.25	1.99
Estimated cost of boarding farm hands by the day.....	.50	.15	.35

Mr. Hamilton explains that each reporter gives the maximum and minimum, the amount between them being the average he submits; that the reports of the 4 reporters in each county are averaged, and that the general average for the State is the sum of the 67 county averages divided by 67. He knows of no statistics showing the relative amounts of high grade and lower priced labor. The general average is found to be nearly the same, year by year. (349, 350.)

Mr. Hamilton explains the divergence between the maximum and minimum wages by saying that Philadelphia County employs market gardeners and florists—more expert labor than the outlying counties—and that the proximity of manufactures and railroad work increases farm wages and takes the best laborers, so that the farmers must content themselves with the lower grade. (349, 350.)

Ohio.—Mr. BRIGHAM says the wages of farm laborers have increased greatly compared with 40 or 50 years ago. At that time in Ohio the best men could be hired for from \$10 to \$12 per month with board. The maximum wage is now \$18 or \$20 a month with board, the average being perhaps \$16 or \$17. The daily wage during the harvest season is from \$1 to \$1.25. Wages do not fluctuate materially with changes in the prices of agricultural products, although when there has been a continued depression of prices it may tend to reduce the general level of wages.

Married men are quite often preferred by employers. In such cases they are usually furnished with houses and are paid by the year at from \$200 to \$250.

Farmers usually pay wages in cash, promptly at the time due, whether by the day, week, or month. (5-9.)

Illinois.—Mr. WILSON testifies (1899) that the maximum farm wages in central Illinois are \$21 to \$22 a month and board, for 9 or 10 months. This is higher than wages were 20 years ago, but in recent years there has been very little difference. When a man is hired by the year he probably gets \$18 and board; some heavy cattle feeders will pay \$20. Payments are in cash almost entirely. Married men get about \$25 a month by the year, with a house, one-fourth or one-half an acre of land, and a cow, or pasture for his own cow, and the use of a team for hauling when needed. Only a few married men will hire for less than a year. (244, 245.)

Minnesota and the Dakotas.—Mr. GREERLEY testifies that farmers in Minnesota and the Dakotas now pay about \$20 to \$25 a month, with board, lodging, etc., or about \$4 or \$5 more than 8 or 10 years ago, on an average. Many pay tried and reliable hands still more. (928.)

Mr. MORAN, of Graceville, Minn., testifies that when he used a McCormick reaper he paid as high as \$3 a day for laborers to bind grain. Farmers now pay from \$2 to \$2.50 during harvest time, which is a short period. The farmers get along during a good deal of the time without farm help, invariably doing the chores themselves during the winter, at least. If they have more stock than they can take care of, they usually hire a man by the year for \$175 to \$200, usually with board. Men hired during harvest by the day are paid from \$2 to \$2.50. Men hired by the month at the busy season usually receive \$20 to \$30 a month and board. Mr. Moran says the farm wages for the yearly laborer have not varied much as compared with 25 or 30 years ago. Mr. Moran worked for less money 40 years ago, however. (711.)

Mr. BUDGE states that the average farm wages in North Dakota are about \$15 a month in the winter, and \$22 and \$25 a month from spring to fall. Payments are made in cash. (846.)

Mr. PROM estimates the average farm wages in North Dakota during the fall to be \$22 a month and board. During harvest the rate fluctuates greatly. The farmers pay up to \$30 a month, and often are unable to hire men by the month and have to pay \$2 to \$2.50 a day. (788.)

Mr. JUMPER, of Aberdeen, S. Dak., says farm wages with board and lodging are from \$200 to \$210 by the year, or 20 per cent higher than 4 years ago (1896-97); about \$20 a month for the 8 summer months, and from \$8 to \$10 for the 4 winter months; and about \$2 to \$2.50 a day for harvest, and \$1.50 for the haying season. (739.)

Maryland.—Mr. AGER testifies that wages for agricultural labor in Maryland are from \$10 to \$15 a month with board, or 75 cents and \$1 a day without board. Men are usually hired by the week, day, or month, very seldom by the year. Wages are paid in cash. It used to be the custom years ago in Maryland to furnish rations to farm laborers, but this is not done much at the present time. (104, 105.)

Virginia.—Mr. WENDERBURN, of Dunn Loring, Va., near Washington, says farm labor in that section of the State is paid 50 cents with board or 75 cents without board. Occasionally a higher price is paid. In harvest the wages run from \$1.50 to \$2 a day. Wages by the month are about \$12, or \$15, or \$16, but wages are generally by the day and are paid weekly in cash. Store orders are now very rarely given. Where the landlord employs a married man by the month or year, he furnishes a tenement house. There is very little white labor. Sometimes a man does partially skilled labor, such as digging ditches or wells, or pruning fruit trees, and gets \$1 a day. (620.)

West Virginia.—Mr. CLORAN, of West Virginia, says farm wages in his locality run from \$8 to \$15 a month, with board, not including washing and mending. Where a man boards himself the wage is 75 cents a day, or \$1 in the busy season. Several farmers pay about \$100 to \$150 a year and furnish a fairly good house, garden, cow-pasture, and perhaps a run for two or three hogs. (592, 593.)

Kentucky.—Mr. NALL testifies that agricultural laborers in Kentucky get from 50 cents to \$1.50 a day, and in rare cases in harvest \$2.50 a day, but not as much as a few years ago. Wages by the month, when the hand is boarded, range from \$11.50 to \$14 and \$15. Wages by the month without board, where the hand lives on the place in a house furnished by the farmer, run from \$15 to \$23. Sometimes a specially good horseman, for instance, will get \$26 or \$27. The average pay where the laborers board themselves, however, runs from \$16.50 to \$19.10 per month. The laborers who board themselves are as a rule housed on the premises rent free, and usually have a pasture for a cow and have their fowls and pigs. (803.)

Mr. Nall adds that as a rule wages are paid in cash, but an employer will sometimes for convenience give store orders. Mr. Nall thinks the stores sell as cheaply when these are presented as if they received cash. (804.)

Mr. Nall says the colored laborer gets as much as the white if he does as much work. The figures given are averages for all labor employed. (815.)

North Carolina.—Mr. WHITE testifies that a great many persons in North Carolina hire themselves out by the day or month to land owners or to very well-to-do tenants who run a four or five horse crop. The wages are usually from 25 to 50 or 60 cents a day, or from \$8 to \$10 a month. Some of the laborers wait until the crop is sold for their pay except food actually consumed; others are paid daily, largely in provisions for their families from the storehouse. The storehouse prices are very high—double city prices. A great many men with families do not get over \$10 a month. Their wives and children are hired out. Their provisions are very coarse, usually corn, a little molasses, and Western side meat. (423.)

South Carolina.—Mr. HAMMOND, a South Carolina cotton planter, says that day wages are 40 to 50 cents, without food, and with or without shelter, garden, and fuel. Monthly wages at the time of his testimony were relatively high, because of the higher price of cotton, ranging from \$7 to \$12, with house, fuel, garden, rations, and

privilege of poultry. Cotton picking is paid for at from 30 to 60 cents a hundred-weight. The wages of domestic servants in towns and of men in stores are much better than the wages of agricultural laborers. But the laborers who live in town and work in the neighboring fields get only common agricultural wages. (820, 821.)

Mr. Hammond says that wages are paid daily, weekly, fortnightly, monthly, and, more rarely, yearly. Monthly and yearly wages are usually paid, one-half at the end of each month and the rest at the end of the year. There is little payment of wages in kind, but more is paid by store orders or advances from the farm commissary than in cash, until the final settlement is made, when cash is given for the balance. Negro laborers have a very clear idea of what is due them, though they may not be able to explain their mathematics. Employers generally settle fairly to avoid the reputation of being bad paymasters, which would interfere with their getting labor. (821.)

Mr. YOUNG, of South Carolina, testifies that he runs his plantation in connection with a store. The store sells goods at 50 per cent profit, and the plantation laborers are paid partly in store orders. All the plowmen get for $5\frac{1}{2}$ days' labor, in addition to 1 peck of meal and 3 pounds of bacon and salt, is 90 cents in trade at the store, and 20 cents in cash. When labor is employed by the day, he pays 30 cents, one-fourth in cash and three-fourths to be traded out at the store. He employs his plowmen by the month, and unless they are prevented by the weather or sickness, they make $5\frac{1}{2}$ days' honest work each week, a little more than slaves did before the war. He allows the hands on his plantation 2 acres of land, and the plowmen have the use of the animals on Saturday evenings, if they are not needed. (117, 118.)

Georgia (see also III F, p. CXXVIII).—Mr. REDDING testifies that farm laborers who work for wages in Georgia receive about \$120 or \$125 a year and rations—4 pounds of bacon and a peck of meal a week. The employer also furnishes the house, garden patch, and fuel free of charge. The men are paid to some extent in cash, and others are paid in supplies; some farmers pay at the end of the year. It is difficult for a man to support a large family on these wages, but a man working only for himself, or for himself and wife, if the wife is willing to work, can lay up something every year. Women are mainly employed in the spring in chopping cotton, and in the fall in gathering cotton, but only men are employed regularly. (448.)

Mr. NUNNALLY, of Georgia, testifies that farm wages in the South range from \$5 to \$8 a month, with board and house room, seldom reaching \$10 a month. If white men are hired in Georgia they are paid \$8 and are furnished a house to live in. (455, 456.)

Mr. BARRETT says that where labor is hired in Georgia it is usually by the month during about 7 months of the year, up to cotton picking time, and the wages range from \$2 to \$6 per month, together with rations, which cost about 35 cents a week. The negro is furnished a house and garden, and may keep pigs, chickens, etc. During the cotton picking season work is by the 100 pounds, the average wage amounting to 50 or 60 cents per day. Some farmers pay their help in store orders, receiving a commission from the storekeeper. (46.)

Mr. HALE, of Fort Valley, Ga., testifies that the maximum wage of colored laborers in that section is \$1 per day, and the lowest for men about 40 cents. The average for men he estimates at not quite 60 cents. The wages of negro women and children vary from 25 to 50 cents, with an average of perhaps $37\frac{1}{2}$ cents. In the fruit and truck business wages are paid weekly, or in a few instances monthly. On the cotton plantations there are irregular payments, whenever a laborer must have money and the employer can pay it, with a final settlement at the end of the year. (377.)

Mr. Hale says a great many store orders are given in the South, because the planters have little ready money, and can arrange with the store to pay at the end of the year. Some supplies are furnished by planters, and some pay cash. The fruit and truck farmers most largely pay cash, because they have cash coming in at various seasons of the year, but some of them pay partially in supplies. Mr. Hale finds that the workers are better satisfied with cash payments. (378, 379.)

Mr. STEVENS testifies that the farm hand in Georgia is furnished a home, a garden, fuel, water, and ordinary rations. The maximum pay in money is \$15 a month, the minimum \$5 a month. Some skilled laborers who understand the use of improved forms of machinery receive as much as \$1 and \$1.50 a day. (907.)

Mr. Stevens says the best method of paying wages is by the month. Some Georgia farmers adopt the plan of paying half the monthly cash wages on the first Saturday of every month and set aside the other half to be paid on the 24th of December, as that would be the only way by which the colored farm hand would have any money at all for Christmas. A few farmers pay weekly, others monthly, while a majority pay a portion of the monthly wages in either cash or trade at the stores. The laborer has a lien for the balance of the money retained, upon the 24th of Decem-

her, on everything that the landlord owns. The law protects the laborer entirely, and the landlord's property can be attached for such a debt anywhere. Moreover, public sentiment sustains the safety of prompt payment of claims of this nature, and a man who would not pay it would not get any more labor at all. The garnishee law does not apply to wages; the law provides that wages for labor of any kind can not be garnisheed. Labor is thus protected in every way, and the result of this kind of payment is that the laborer has a sort of forced saving made for him by the landlord. If it were not for this plan the colored laborers, as a rule, would spend every cent of money they receive just as fast as they make it. Some of them, however, are industrious and economical, and succeed in life very well, attending to their own business and making money. (906, 907, 910.)

Mr. PEEK, of Georgia, hires both white and colored farm laborers and pays \$10 a month and rations—about 15 pounds of bacon, a bushel of meal, and a gallon of sirup a month. He also provides furnished houses and garden patches and firewood. He thinks that counting the house rent, rations, etc., the remuneration is equivalent to about \$15 a month. It is customary to employ all the wives and children on the farm the year round. (460, 461.)

Alabama.—Mr. POOLS testifies that agricultural labor in Alabama is better provided for and receives better returns than it did 15 or 20 years ago, and that it is less migratory. The maximum wages for agricultural laborers in Alabama are about \$10 a month, and the minimum about \$6, for farm laborers with their provisions and tenant houses furnished. Wages are generally paid half cash monthly. (918, 924.)

Mississippi.—Mr. KYLE says men are very rarely found working on farms in Mississippi for wages. Those hired in that way are paid from \$6 to \$15 a month and found. (471, 474.)

Tennessee.—Mr. GODWIN, of Tennessee, pays his colored tenants for casual labor 50 cents a day, without board. (475.)

Mr. MANSON, of Saulsbury, Tenn., pays about \$8 a month for hired help, and furnishes houseroom, firewood, and cooked food. (506.)

Mr. HILL, who owns a plantation near Memphis, Tenn., pays his laborers \$10 a month and provides houseroom, wood, and cooked meals. (505.)

Mr. NORFLEET, of Memphis, testifies that farm wages in the uplands are about 50 cents a day, and in the Mississippi bottom about 75 cents a day. Houses and all the ordinary farm comforts are provided. He thinks labor is better off in the South now than ever before since the war. (485.)

Mr. GAGE, of Memphis, says his customers sometimes pay the laborers so much to work the crop and "lay it by" (meaning that the crop is finished and waiting for the warm sun of June, July, and August to mature the cotton); then the owner pays generally from 40 to 50 cents a hundred pounds for picking. Men employed by the day are paid in the neighborhood of 60, 65, or 75 cents a day in some places; in other places not more than 50 cents. The food is not included in these prices, but the owner sells it to the laborers; he generally keeps a storeroom, and on Saturdays the laborers come and get meat, meal, tobacco, molasses, and other necessities. Men who look after the mules are employed by the month. The owner generally furnishes a good house and an acre or half-acre of ground for a garden, and gives the laborers the privilege of cutting wood. (492.)

Arkansas.—Mr. BALCH, of Little Rock, Ark., testifies that 75 cents a day, without board but with free house rent and fuel, is the customary wage for farm labor in his community. In 1899 some were paid 40 cents a day and boarded. (496.)

Louisiana.—Dr. STUBBS says \$1 to \$1.25 is about the average daily pay for a laborer in Louisiana, where they are employed by the day. A house, garden, firewood, etc. are furnished, but not rations. In the cane fields from 75 cents to \$1.50 is paid. On the cotton plantations there are no regular wages (see II C 2, p. —), but the few white farmers who hire for wages usually feed the laborers from their tables and pay from \$8 to \$15 a month. As a rule, however, the wages are so much a day for chopping cotton and so much for picking cotton. (777.)

Plantation stores.—Dr. STUBBS says that nearly every large sugar estate has a store. A timekeeper gives each workman a metal or a horn token representing a day's work and receivable at the store. Everyone on a sugar plantation is paid off on the 15th and 30th of the month; but "if he has spent his chips, as the tokens are called, he does not get his money."

Dr. Stubbs says only the large rice planters run stores in connection with their plantations. (777.)

3. Special forms of compensation.—*Acreeage plan* (see also *Thinning sugar beets*, III F 2, p. cccxix).—Mr. NORFLEET, of Memphis, testifies that in the Mississippi bottom, where cotton is cultivated under the acreage plan, the laborer is paid \$4 to \$5 an acre for his labor. The landlord furnishes the team, feed, implements, and seed. (489.)

privilege of poultry. Cotton picking is paid for at from 30 to 60 cents a hundred-weight. The wages of domestic servants in towns and of men in stores are much better than the wages of agricultural laborers. But the laborers who live in town and work in the neighboring fields get only common agricultural wages. (820, 821.)

Mr. Hammond says that wages are paid daily, weekly, fortnightly, monthly, and, more rarely, yearly. Monthly and yearly wages are usually paid, one-half at the end of each month and the rest at the end of the year. There is little payment of wages in kind, but more is paid by store orders or advances from the farm commissary than in cash, until the final settlement is made, when cash is given for the balance. Negro laborers have a very clear idea of what is due them, though they may not be able to explain their mathematics. Employers generally settle fairly to avoid the reputation of being bad paymasters, which would interfere with their getting labor. (821.)

Mr. YOUNG, of South Carolina, testifies that he runs his plantation in connection with a store. The store sells goods at 50 per cent profit, and the plantation laborers are paid partly in store orders. All the plowmen get for $5\frac{1}{2}$ days' labor, in addition to 1 peck of meal and 3 pounds of bacon and salt, is 90 cents in trade at the store, and 20 cents in cash. When labor is employed by the day, he pays 30 cents, one-fourth in cash and three-fourths to be traded out at the store. He employs his plowmen by the month, and unless they are prevented by the weather or sickness, they make $5\frac{1}{2}$ days' honest work each week, a little more than slaves did before the war. He allows the hands on his plantation 2 acres of land, and the plowmen have the use of the animals on Saturday evenings, if they are not needed. (117, 118.)

Georgia (see also III F, p. CXXVIII).—Mr. REDDING testifies that farm laborers who work for wages in Georgia receive about \$120 or \$125 a year and rations—4 pounds of bacon and a peck of meal a week. The employer also furnishes the house, garden patch, and fuel free of charge. The men are paid to some extent in cash, and others are paid in supplies; some farmers pay at the end of the year. It is difficult for a man to support a large family on these wages, but a man working only for himself, or for himself and wife, if the wife is willing to work, can lay up something every year. Women are mainly employed in the spring in chopping cotton, and in the fall in gathering cotton, but only men are employed regularly. (448.)

Mr. NUNNALLY, of Georgia, testifies that farm wages in the South range from \$5 to \$8 a month, with board and house room, seldom reaching \$10 a month. If white men are hired in Georgia they are paid \$8 and are furnished a house to live in. (455, 456.)

Mr. BARRETT says that where labor is hired in Georgia it is usually by the month during about 7 months of the year, up to cotton picking time, and the wages range from \$2 to \$6 per month, together with rations, which cost about 35 cents a week. The negro is furnished a house and garden, and may keep pigs, chickens, etc. During the cotton picking season work is by the 100 pounds, the average wage amounting to 50 or 60 cents per day. Some farmers pay their help in store orders, receiving a commission from the storekeeper. (46.)

Mr. HALE, of Fort Valley, Ga., testifies that the maximum wage of colored laborers in that section is \$1 per day, and the lowest for men about 40 cents. The average for men he estimates at not quite 60 cents. The wages of negro women and children vary from 25 to 50 cents, with an average of perhaps $37\frac{1}{2}$ cents. In the fruit and truck business wages are paid weekly, or in a few instances monthly. On the cotton plantations there are irregular payments, whenever a laborer must have money and the employer can pay it, with a final settlement at the end of the year. (377.)

Mr. Hale says a great many store orders are given in the South, because the planters have little ready money, and can arrange with the store to pay at the end of the year. Some supplies are furnished by planters, and some pay cash. The fruit and truck farmers most largely pay cash, because they have cash coming in at various seasons of the year, but some of them pay partially in supplies. Mr. Hale finds that the workers are better satisfied with cash payments. (378, 379.)

Mr. STEVENS testifies that the farm hand in Georgia is furnished a home, a garden, fuel, water, and ordinary rations. The maximum pay in money is \$15 a month, the minimum \$5 a month. Some skilled laborers who understand the use of improved forms of machinery receive as much as \$1 and \$1.50 a day. (907.)

Mr. Stevens says the best method of paying wages is by the month. Some Georgia farmers adopt the plan of paying half the monthly cash wages on the first Saturday of every month and set aside the other half to be paid on the 24th of December, as that would be the only way by which the colored farm hand would have any money at all for Christmas. A few farmers pay weekly, others monthly, while a majority pay a portion of the monthly wages in either cash or trade at the stores. The laborer has a lien for the balance of the money retained, upon the 24th of Decem-

wood choppers, etc., \$372; miners, \$420; those engaged in manufacturing and mechanical industries, \$445; fishermen, \$225. (153.)

Mr. KERRICHUM says mechanics' wages are higher than those of farm laborers, because they work by the day, but comparing earnings for the entire year, he thinks the farm hand is in about as good a position as the mechanic. He does not think the average labor on a farm the year through is any harder than that of a mechanic working ten hours a day, but mentions truckers and dairymen as working harder than the average farmer. (137.)

6. *Savings of farm laborers.*—Mr. MORAN, of Minnesota, says the young man who gets \$200 a year and board on a farm, after paying for his clothing, shoes, washing, and incidental expenses, may possibly have a trifle left at the end of the year; if he is careful, it may be \$100. (711.)

Mr. GREELEY, of South Dakota, says a married farm laborer, with a small piece of land to cultivate, can lay up more money than one employed in the city at much higher wages. Mr. Greeley knows of cases where men whose wives worked with them lay up all their wages. They have chickens to pay the grocery bill, and possibly two cows, which almost support the family. Mr. Greeley knows several families who sell enough butter and eggs to provide all their clothing and living, and very often more than the wages are saved at the end of the year. This kind of living engenders a wholesome independence and self-reliance. Such persons almost invariably become owners of land, and they are twice as apt to succeed as men from the city who know nothing about farming. Their work is a valuable education, the lack of which so frequently wrecks the beginner. They almost invariably make good farmers and intelligent citizens. (928, 929.)

E. Housing of laborers and tenants (see also *Scarcity of farm labor*, III B 5, p. cxix).—Mr. HALE says it is the general custom of the South to furnish laborers with tenant houses with about 2 to 3 acres of land and fuel, usually without charge; in some instances 2 days' work a month pays the rent. (379.)

Mr. Hale says the original plantation houses of the South were for the most part 1-room affairs of logs, 20 or 25 feet square. The modern house is a frame house, boarded and sheathed, with 3 rooms. (384.)

Mr. AGER testifies that most farmers in Maryland have tenant houses on their places. They are usually small (about 3 rooms), but quite comfortable, and are lathed and plastered. There is generally a garden spot of perhaps a quarter of an acre, more than most of the tenants will cultivate. The owner of the farm usually plows the garden, and the tenants work it at night or early in the morning; their wives generally do more of it than the men. They raise a few garden vegetables, potatoes and corn, and possibly some watermelons. Some classes of tenants, like the Germans in the West, would raise enough vegetables to support themselves on a piece of ground of that size, but the colored tenants do not. The laborers are not, as a general thing, given time on Saturday afternoons to cultivate their gardens, though the aim is to get through a little earlier on Saturday night than on other nights, and they do not work in their gardens on Sunday. Mr. Ager has 3 tenements on his place, and hoped thereby to secure some reliable help, but was mistaken. None of his tenants are employed on his farm; they go to some one else. He charges \$4 a month rent, and the tenants have the use of such down fuel as they may pick up about the place. (104, 105.)

Mr. WHITE testifies that probably over half of the farm tenants of North Carolina are very poor. They are huddled together in small houses of 1, 2, or 3 rooms, sometimes 8 or 10 in the family. Poverty, he says, always begets degradation and immorality. (420.)

Mr. HAMMOND, of South Carolina, says that the negro prefers an isolated house. The houses now built are much more comfortable than they have been before since slavery times. Log houses have gone out entirely. The dirt floor has not been commonly used in 60 years. Houses are now coming to be generally provided with glass windows. The tenement house is likely to have a front room 18 by 20, with two shed rooms 15 by 20 for bedrooms. These 2 and 3 room houses, with fuel and a garden plot of an acre or less, rent for \$2 a month, or a day's work a week. Such a house costs from \$85 to \$150. Lumber and carpenter work are very cheap. (821.)

Mr. Hammond admits that the negroes would probably prefer that their cottages be somewhat near together in the farming neighborhoods, if they were policed, as under the old plantation system. In the Southern towns the negro quarters are as marked features as the Jews' ghettos anywhere in Europe. There they get along tolerably well, but they have police to keep the peace. (822.)

Mr. STEVENS, of Georgia, says there has been considerable improvement in the last 20 years in the homes of the colored people. The landlords have been forced to

privilege of poultry. Cotton picking is paid for at from 30 to 60 cents a hundred-weight. The wages of domestic servants in towns and of men in stores are much better than the wages of agricultural laborers. But the laborers who live in town and work in the neighboring fields get only common agricultural wages. (820, 821.)

Mr. Hammond says that wages are paid daily, weekly, fortnightly, monthly, and, more rarely, yearly. Monthly and yearly wages are usually paid, one-half at the end of each month and the rest at the end of the year. There is little payment of wages in kind, but more is paid by store orders or advances from the farm commissary than in cash, until the final settlement is made, when cash is given for the balance. Negro laborers have a very clear idea of what is due them, though they may not be able to explain their mathematics. Employers generally settle fairly to avoid the reputation of being bad paymasters, which would interfere with their getting labor. (821.)

Mr. YOUNG, of South Carolina, testifies that he runs his plantation in connection with a store. The store sells goods at 50 per cent profit, and the plantation laborers are paid partly in store orders. All the plowmen get for $5\frac{1}{2}$ days' labor, in addition to 1 peck of meal and 3 pounds of bacon and salt, is 90 cents in trade at the store, and 20 cents in cash. When labor is employed by the day, he pays 30 cents, one-fourth in cash and three-fourths to be traded out at the store. He employs his plowmen by the month, and unless they are prevented by the weather or sickness, they make $5\frac{1}{2}$ days' honest work each week, a little more than slaves did before the war. He allows the hands on his plantation 2 acres of land, and the plowmen have the use of the animals on Saturday evenings, if they are not needed. (117, 118.)

Georgia (see also III F, p. CXXVIII).—Mr. REDDING testifies that farm laborers who work for wages in Georgia receive about \$120 or \$125 a year and rations—4 pounds of bacon and a peck of meal a week. The employer also furnishes the house, garden patch, and fuel free of charge. The men are paid to some extent in cash, and others are paid in supplies; some farmers pay at the end of the year. It is difficult for a man to support a large family on these wages, but a man working only for himself, or for himself and wife, if the wife is willing to work, can lay up something every year. Women are mainly employed in the spring in chopping cotton, and in the fall in gathering cotton, but only men are employed regularly. (448.)

Mr. NUNNALLY, of Georgia, testifies that farm wages in the South range from \$5 to \$8 a month, with board and house room, seldom reaching \$10 a month. If white men are hired in Georgia they are paid \$8 and are furnished a house to live in. (455, 456.)

Mr. BARRETT says that where labor is hired in Georgia it is usually by the month during about 7 months of the year, up to cotton picking time, and the wages range from \$2 to \$6 per month, together with rations, which cost about 35 cents a week. The negro is furnished a house and garden, and may keep pigs, chickens, etc. During the cotton picking season work is by the 100 pounds, the average wage amounting to 50 or 60 cents per day. Some farmers pay their help in store orders, receiving a commission from the storekeeper. (46.)

Mr. HALE, of Fort Valley, Ga., testifies that the maximum wage of colored laborers in that section is \$1 per day, and the lowest for men about 40 cents. The average for men he estimates at not quite 60 cents. The wages of negro women and children vary from 25 to 50 cents, with an average of perhaps $37\frac{1}{2}$ cents. In the fruit and truck business wages are paid weekly, or in a few instances monthly. On the cotton plantations there are irregular payments, whenever a laborer must have money and the employer can pay it, with a final settlement at the end of the year. (377.)

Mr. Hale says a great many store orders are given in the South, because the planters have little ready money, and can arrange with the store to pay at the end of the year. Some supplies are furnished by planters, and some pay cash. The fruit and truck farmers most largely pay cash, because they have cash coming in at various seasons of the year, but some of them pay partially in supplies. Mr. Hale finds that the workers are better satisfied with cash payments. (378, 379.)

Mr. STEVENS testifies that the farm hand in Georgia is furnished a home, a garden, fuel, water, and ordinary rations. The maximum pay in money is \$15 a month, the minimum \$5 a month. Some skilled laborers who understand the use of improved forms of machinery receive as much as \$1 and \$1.50 a day. (907.)

Mr. Stevens says the best method of paying wages is by the month. Some Georgia farmers adopt the plan of paying half the monthly cash wages on the first Saturday of every month and set aside the other half to be paid on the 24th of December, as that would be the only way by which the colored farm hand would have any money at all for Christmas. A few farmers pay weekly, others monthly, while a majority pay a portion of the monthly wages in either cash or trade at the stores. The laborer has a lien for the balance of the money retained, upon the 24th of Decem-

ners and pick them up one by one; he goes to a Chinese labor bureau, or usually to one of the Six Companies, who are always prepared to contract for any number of men, and hires the number he wants, to begin at a given date. They are the best fruit packers in California. Fruit growers in central California say it would be practically impossible to harvest their crops without the Chinamen; they can not find other people who will do the work properly. Cannerymen also say it would be impossible to run their canneries without Chinamen, without being continually harassed by strikes and shortage of labor. The pay of the Chinese laborers is usually received by the person contracting for their employment, or by the foreman of the squad. Mr. Naftzger thinks this is a purely voluntary arrangement; he knows that the Chinamen so engaged always have money Saturday night to gamble with all night or all day Sunday. There are many instances in which Chinamen are employed singly on farms. (954.)

Mr. Naftzger says sometimes fruit packing is done by the package, but as a rule the wages of Chinamen in fruit growing and packing, etc., are about \$1.25 a day, while white men's wages would be \$1.50 to \$1.75. Wages by the day are without board. Farm and ranch (orchard) laborers receive \$25 to \$40 a month, the year round. Where contracts are made for large numbers of Chinamen on certain classes of improvements, Mr. Naftzger thinks they are obtained as low as \$1 a day; and he thinks they live on as little as 25 cents a day. The Chinamen do more or less contract work; in some instances they are section men on the railroads, but Mexicans are used more for that purpose. (955.)

Mr. Naftzger says that when the Chinese are engaged in contract work or ranch work they invariably feed themselves, and usually rice is the chief article of diet. When they go into the city they eat meat, especially pork, and fish. (954.)

2. Thinning sugar beets.—Mr. ROGERS, president of the Binghamton Beet Sugar Company, says he hires boys or Italians to thin sugar beets. All the help necessary can be obtained in Binghamton. In 1899 he established a tent on the river bank, and the boys regarded it as a sort of a picnic. He paid from 50 cents to \$1.25 a day of 10 hours, charged 10 cents a meal, and lodged the boys under the tent. He estimates that it cost about \$6 an acre to thin the beets. (555, 556.)

Professor KENZIE testifies that in Bay City Polish women and children have been employed very largely for weeding out sugar beets; they are very efficient, and work very cheaply. Professor Kenzie mentions one farmer who paid \$14 an acre for thinning, while another employed Poles at \$4 an acre. (547.)

Mr. SAYLOR testifies that the California planters contract with the laborers for bunching, thinning, hoeing, weeding, harvesting, and piling sugar beets at so much an acre, the contract being made either with individuals, or several in combination, or with a man who furnishes a group of laborers. That kind of labor is nearly all done by Chinese and Japanese. (590.)

Mr. SMITH says that in 1898 beet raisers in Michigan found it possible to hire women to thin beets at from 50 to 65 cents a day; but later in the season, as the supply proved inadequate, these women, and children as well, received from 75 cents to \$1 a day. In 1899, in the same locality, they habitually received \$1 a day and dinner. At Benton Harbor the price rose to \$1.25 and board, and about all the factories in the very busy season the wages rapidly rose to \$1 a day and upward. (574.)

3. Thrashing crews.—Mr. BUDGE says the operators of thrashing machines in North Dakota furnish their own crews. They take their kitchens and cooks with them and board their hands. The operator and his men lodge in the straw stack or the cooking shanty. The thrashing is done for so much a bushel. (851.)

G. Labor of women and children.—1. *On Southern farms.*—Mr. GODWIN, of Tennessee, says that women and children do most of the hoeing of cotton. After the hoe work is done there is no other work they can do until the cotton is ready to pick. They commence picking about the middle of September. The work is light, and the children do not hurt themselves.

Mr. HAMMOND, of South Carolina, states that the negro women work only during certain seasons of the year, as cotton picking and cotton hoeing. (816.)

Child labor on Southern farms.—Mr. GRAHAM, of North Carolina, testifies that children work on the farms from the age of 8. A boy of 10 is as good a plow hand as a man. They pick cotton from the age of 6. Girls hoe and pick cotton. This labor of children is general in both races. (439.)

Mr. GAGE, of Memphis, says a boy 15 years old is big enough to pick cotton, and generally does so, but is not strong enough to plow and to hoe. Mr. Gage has never seen children 9 or 10 years old working in the field, so far as he knows. (494.)

Mr. EDMONDSON, a negro farmer of Tennessee, says that boys who work in the field will never go to the workhouse or the penitentiary. He has 8 boys, of whom 3 are

of age, and the others are working for him. He also worked his daughters in the field as long as they were with him. He testifies that children are a material help; that he would not have been able to accumulate as much as he has without them. (502.)

2. Domestic service.—Mr. GREELEY says that, as a rule, unless there are grown-up daughters, there is little help for the wife and mother in farm homes, principally because none can be had; but very frequently the wife of a tenant hired man is glad to help in trying times and earn a few dollars of her own. The grown girls of such families can also generally be induced to help when needed, though they might not be willing to hire out regularly to strange families; and they may thus become good housekeepers. This repeatedly works greatly to the mutual advantage of all concerned. (929.)

Mr. KERCHUM, of Pennington, N. J., says there are in that vicinity a good many female servants from the South, a great many of whom marry and live there permanently. (133.)

Mr. HAMMOND, of South Carolina, says that in Augusta the wages of a housemaid or a cook range from \$8 to \$15 a month, and those of house servants sometimes go as high as \$20. The better class of servants go to the winter resorts of the South, and in summer to the summer resorts of the North. In this way they make very good wages. (820.)

H. General considerations respecting labor.—1. *Desirability of agricultural labor.*—Professor DAVENPORT does not consider agricultural labor drudgery. He regards the position of a farm laborer as infinitely better than that of a day laborer, plasterer, or mason in the city. (256.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, thinks men accept farm service as a rule because they are not in a condition to go abroad and do better, but adds that the precarious character of mill work and of mining has its effect in making men willing to accept a lower per diem wage in the country; the mine or manufacturing establishment may shut down and leave them without occupation for a period, and living under expensive conditions. (350.)

Mr. HANLEY says there is not so much drudgery in farm labor as there was in the early days. (274.)

2. Labor organizations and disputes.—Mr. POOLE says that in Alabama, as elsewhere, the agricultural labor is so scattering it does not strike. Strikes in other industries have been very rare in Alabama. There has been only one serious strike in the mill districts, and that was years ago. The question of compulsory arbitration has not been agitated. (925.)

Referring to the controversies between capital and labor, Mr. RICHARDS, a Chicago grain merchant, says wrong exists on both sides. As a remedy he proposes a national law authorizing labor organizations to be created, with as many subordinate classified branches as they may require, under a department of the Government. The present labor organizations have no legal entity. We have organized capital against disorganized labor; both should be on the same footing. (207, 208.)

3. Enticing laborers away.—Mr. HALE says Georgia has a law against enticing laborers away from their employment, but he does not think it amounts to very much. It was probably framed because of the traveling black missionaries who raised discontent among the hands with colonization schemes. There was a class of tramp negroes who were not industrious and found it easier to live by trying to move others than by doing anything themselves. Mr. Hale thinks in general that the law is not unjust and has accomplished some good. (379.)

4. The Southern attitude toward manual labor.—Mr. POOLE, of Alabama, says that among the old aristocracy of the South there was a tendency to look down upon the trades, but that is gradually disappearing and many of the best young men are going into trades. A neighbor of Mr. Poole's, who is a wealthy cotton mill owner, has a son at Lowell learning the textile industry. This is mentioned as one of numerous instances. Mr. Poole says there is in the South a very liberal disposition toward the mechanical trades. (921, 922.)

Dr. STUBBS says that not only is it respectable for white men to work with their hands in Louisiana, but some of the best and wealthiest men do so, and such labor is the admiration of everyone in that country. Dr. Stubbs has seen a millionaire's son plowing with a 4-mule plow.

Before the civil war there was no necessity for such labor, but there has always been a feeling among all Southern people that they should do the work when there was necessity. Even before the war Dr. Stubbs has seen the children of wealthy and aristocratic farmers who had gone to pieces financially take to hard work like negroes, and yet be received in the best society as always before. Dr. Stubbs remarks that a man who can make use of hired labor to do the work, whether he is from the

North or the South, is very apt not to do it himself, but to turn his attention to something more profitable. The Californians use the Chinese just as the negroes are used in the South. Dr. Stubbs believes every man should labor when there is necessity, however, and says he himself has done as much hard work as any working man in the North. (778.)

5. *Iron law of wages.*—Mr. REDDING, director of the Georgia Experiment Station, thinks the wages of common physical labor everywhere are down at the point of actual subsistence, and that no man rises above that level unless he becomes skilled and displays energy and ambition. (445)

IV. PROBLEMS OF RACE AND IMMIGRATION.

A. Number of negroes in certain States.—*North Carolina.*—Mr. WHITE says that eliminating South Carolina and Mississippi there are very few communities in the South where the negro is in the majority. In North Carolina there are 2½ whites to every colored person. Out of 96 counties only 8 or 9 have a negro majority. Mr. White says he was sent to Congress partly by white votes. (429, 430.)

Mr. GRAHAM estimates that one-third of the population of North Carolina is colored, and that the negroes own \$3,000,000 out of \$200,000,000. The poll tax is the same for both races. Two-thirds of it goes to the schools, and the other third to the poorhouses or county homes. (438.)

South Carolina.—Mr. DUNCAN, of Newberry, S. C., testifies that there are in South Carolina about 400,000 whites and a little over 600,000 negroes; the ratio is about 3 to 2. (518.)

Alabama.—Mr. POOLE, Commissioner of Agriculture of Alabama, testifies that about 50 per cent of those engaged in agricultural labor in Alabama are colored. A very small percentage of these own their property. Of the different modes of farming, tenancy, sharing or partnerships, and the wage system are about equally represented. There are about 18 Black Belt counties crossing Alabama from east to west, in which the soil generally is black and the population largely colored, the negroes outvoting the whites 5 or 6 to 1. (918, 919.)

New York.—Mr. NORRIS says there are very few colored people in the State of New York. When the slaves were freed in New York, the Fitzhugh family, of Sodus, gave their slaves about 1,000 acres, but the negroes, though having this land given them, still live in little hovels, and have made no progress whatever. They have decreased in numbers fully one-half; some of them have gone away. They do not seem to have any inclination for education, though they could go to school with the whites if they desired. They are indolent, and there is not a single good farmer in the lot. (324.)

B. Unfortunate characteristics of the negro race.—Mr. BROWN says the negroes are accommodating, good natured, and naturally polite, but careless and improvident. They are much inclined to drinking, and have little regard for morals generally. The large proportion of Georgia counties which have adopted local prohibition is explained by the desire to prevent the negroes from obtaining whisky. Most of the terrible outrages committed by the negroes are due to the influence of drink.

Another injurious effect from the presence of negroes is that the whites come to consider farm work as menial. They prefer to live in the towns on air and water rather than to work on farms at a fair pay.

Mr. Brown does not know whether it will be possible to make the negroes prosperous and self-sustaining by technical and industrial education. Even though having a reasonable education, they seldom succeed for any length of time. They are contrasted with the whites, who, though having little education or capital, gradually rise from year to year after they once get a start. Very few negroes are landholders, and the experience of 35 years of liberty shows doubtful indication of capacity for progress. (65, 66.)

1. *Indolence and unreliability.*—Mr. GRAHAM testifies that a good white man is a better tenant than a good negro, but a good negro is much better than a mean white man. He thinks a larger percentage of the negroes than of the white men are indolent. Some of the negroes are as reliable as anyone, but most of them are more unreliable than white men. Mr. Graham does not think that the negro has improved as a farmer since his emancipation. One of the old slaves who was taught farming under an overseer or owner is a better farmer to-day than the younger men, with some exceptions. Among the slaves there were also blacksmiths and carpenters as good as those of to-day. (434.)

of age, and the others are working for him. He also worked his daughters in the field as long as they were with him. He testifies that children are a material help; that he would not have been able to accumulate as much as he has without them. (502.)

2. Domestic service.—Mr. GREELEY says that, as a rule, unless there are grown-up daughters, there is little help for the wife and mother in farm homes, principally because none can be had; but very frequently the wife of a tenant hired man is glad to help in trying times and earn a few dollars of her own. The grown girls of such families can also generally be induced to help when needed, though they might not be willing to hire out regularly to strange families; and they may thus become good housekeepers. This repeatedly works greatly to the mutual advantage of all concerned. (929.)

Mr. KERCHUM, of Pennington, N. J., says there are in that vicinity a good many female servants from the South, a great many of whom marry and live there permanently. (133.)

Mr. HAMMOND, of South Carolina, says that in Augusta the wages of a housemaid or a cook range from \$8 to \$15 a month, and those of house servants sometimes go as high as \$20. The better class of servants go to the winter resorts of the South, and in summer to the summer resorts of the North. In this way they make very good wages. (820.)

H. General considerations respecting labor.—1. *Desirability of agricultural labor.*—Professor DAVENPORT does not consider agricultural labor drudgery. He regards the position of a farm laborer as infinitely better than that of a day laborer, plasterer, or mason in the city. (256.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, thinks men accept farm service as a rule because they are not in a condition to go abroad and do better, but adds that the precarious character of mill work and of mining has its effect in making men willing to accept a lower per diem wage in the country; the mine or manufacturing establishment may shut down and leave them without occupation for a period, and living under expensive conditions. (350.)

Mr. HANLEY says there is not so much drudgery in farm labor as there was in the early days. (274.)

2. Labor organizations and disputes.—Mr. POOLE says that in Alabama, as elsewhere, the agricultural labor is so scattering it does not strike. Strikes in other industries have been very rare in Alabama. There has been only one serious strike in the mill districts, and that was years ago. The question of compulsory arbitration has not been agitated. (925.)

Referring to the controversies between capital and labor, Mr. RICHARDS, a Chicago grain merchant, says wrong exists on both sides. As a remedy he proposes a national law authorizing labor organizations to be created, with as many subordinate classified branches as they may require, under a department of the Government. The present labor organizations have no legal entity. We have organized capital against disorganized labor; both should be on the same footing. (207, 208.)

3. Enticing laborers away.—Mr. HALE says Georgia has a law against enticing laborers away from their employment, but he does not think it amounts to very much. It was probably framed because of the traveling black missionaries who raised discontent among the hands with colonization schemes. There was a class of tramp negroes who were not industrious and found it easier to live by trying to move others than by doing anything themselves. Mr. Hale thinks in general that the law is not unjust and has accomplished some good. (379.)

4. The Southern attitude toward manual labor.—Mr. POOLE, of Alabama, says that among the old aristocracy of the South there was a tendency to look down upon the trades, but that is gradually disappearing and many of the best young men are going into trades. A neighbor of Mr. Poole's, who is a wealthy cotton mill owner, has a son at Lowell learning the textile industry. This is mentioned as one of numerous instances. Mr. Poole says there is in the South a very liberal disposition toward the mechanical trades. (921, 922.)

Dr. STUBBS says that not only is it respectable for white men to work with their hands in Louisiana, but some of the best and wealthiest men do so, and such labor is the admiration of everyone in that country. Dr. Stubbs has seen a millionaire's son plowing with a 4-mule plow.

Before the civil war there was no necessity for such labor, but there has always been a feeling among all Southern people that they should do the work when there was necessity. Even before the war Dr. Stubbs has seen the children of wealthy and aristocratic farmers who had gone to pieces financially take to hard work like negroes, and yet be received in the best society as always before. Dr. Stubbs remarks that a man who can make use of hired labor to do the work, whether he is from the

4. Improvidence.—Mr. POOLE, of Alabama, testifies that as a general thing the white farmers are more thrifty than the negroes. The negro share cropper, working 1 mule, will draw on account, perhaps, 100 or 150 bushels of corn for his family. If he wants a pound of coffee or a little sugar he will sell a bushel of corn to get it at a near-by country store, and generally by the 1st of March he is out of provisions and has to go to his landlord for them. The country merchant puts a very low price on the corn, but as soon as it is out of the hands of the negro it increases in value. The corn is generally bought by the smaller cross-roads storekeeper, while advances are generally furnished by the larger stores in the towns and villages. Mr. Poole says the merchant is human and gets all the profit he can, but there has been an improvement in this respect, and the condition of the negro has improved correspondingly. He thinks advances are furnished as reasonably as could be expected under the circumstances. The merchant takes a mortgage lien on the cropper's interest in the crop, frequently asking the landlord what amount he considers him good for, and holding him down to a certain amount until the crop shows what it is going to do. When the negroes make a settlement at the end of the year they go and buy whatever they want—furniture, guns, horses, wagons, buggies, etc., and generally get rid of their money very rapidly. If they were as economical as the whites they would own the Black Belt in a few years. (925, 926.)

Mr. HALE says it is the hardest thing in the world for a darkey to keep money. He urges his laborers to save part of their wages, and encourages them to buy household furniture or other staple necessities with it. In that way they are furnishing their houses a little better each year. They take fairly good care of their tenant houses, and were glad to paint them when he offered to furnish the paint. While entertaining a high opinion of the negroes as laborers, Mr. Hale admits that they are very careless about leaving their tools "anywhere and everywhere." (384.)

Dr. STUBBS says the Louisiana negroes do not want to spend any money on what might be called unessential improvements, and prefer natural luxuries to the artificial ones. (778.)

Mr. NUNNALLY remarks that when the slaves were freed they were thrown upon their own resources from a position in which they had been fed and clothed without care or forethought on their part. The negroes love a good time and are the happiest, most carefree people in the world; with plenty to eat and wear and a few dollars to spend at Christmas, they reach the height of their ambition. Not one in a thousand cares to provide for to-morrow, and but little progress has been made in accumulating wealth. Very few own homes of their own. (454, 455.)

C. Progress of the negroes.—1. *Intelligence and general condition.*—Mr. HALE thinks that around the large cities and towns where the negro has come into too close contact with the white folks, he has perhaps deteriorated, but in 10 years of agricultural work in the Black Belt of Georgia he has seen a very marked improvement in the intelligence, general appearance, and efficiency of the negroes. (400.)

Mr. POOLE testifies that the colored man in the Black Belt is well fed and clothed, law abiding, and well adapted to agriculture. The South seems to be his home. The colored people there come in contact with those who owned them when they were slaves, or their descendants. They are obedient and respectful, and there have never been any labor troubles. There is very little migratory labor in the Black Belt. (919.)

Mr. WHITE testifies that up to 1898 the condition of colored people in North Carolina was decidedly on the upper trend. The best feeling he had ever known in the South existed between the whites and colored people in that State. A large majority of the whites are kindly disposed to the colored man, as shown by their paying without a murmur the bulk of the school tax; but politics has made the situation bad for the negroes. (426.)

Intelligence and capability of negroes.—Mr. DILLINGHAM believes there is more intelligence in the American negroes than in any other black people in a civilized country. (167.)

Mr. HALE thinks the negro children are as bright as the average children of any nationality under similar conditions, and capable of a reasonable amount of education. (385.)

Mr. WHITE says that perfect equality of the two races, either in education, industry, or politics, is next to impossible. The white man's superior civilization for generations, and his supremacy, wealth, and education, will tend to keep the colored man his inferior; but the negroes and whites are dependent upon each other. (428.)

Mr. HAMMOND says that negroes with equal opportunities learn as readily as white people. His children have given lessons to the domestic servants, and have found

of age, and the others are working for him. He also worked his daughters in the field as long as they were with him. He testifies that children are a material help; that he would not have been able to accumulate as much as he has without them. (502.)

2. Domestic service.—Mr. GREELEY says that, as a rule, unless there are grown-up daughters, there is little help for the wife and mother in farm homes, principally because none can be had; but very frequently the wife of a tenant hired man is glad to help in trying times and earn a few dollars of her own. The grown girls of such families can also generally be induced to help when needed, though they might not be willing to hire out regularly to strange families; and they may thus become good housekeepers. This repeatedly works greatly to the mutual advantage of all concerned. (929.)

Mr. KERCHUM, of Pennington, N. J., says there are in that vicinity a good many female servants from the South, a great many of whom marry and live there permanently. (133.)

Mr. HAMMOND, of South Carolina, says that in Augusta the wages of a housemaid or a cook range from \$8 to \$15 a month, and those of house servants sometimes go as high as \$20. The better class of servants go to the winter resorts of the South, and in summer to the summer resorts of the North. In this way they make very good wages. (820.)

H. General considerations respecting labor.—1. *Desirability of agricultural labor.*—Professor DAVENPORT does not consider agricultural labor drudgery. He regards the position of a farm laborer as infinitely better than that of a day laborer, plasterer, or mason in the city. (256.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, thinks men accept farm service as a rule because they are not in a condition to go abroad and do better, but adds that the precarious character of mill work and of mining has its effect in making men willing to accept a lower per diem wage in the country; the mine or manufacturing establishment may shut down and leave them without occupation for a period, and living under expensive conditions. (350.)

Mr. HANLEY says there is not so much drudgery in farm labor as there was in the early days. (274.)

2. Labor organizations and disputes.—Mr. POOLE says that in Alabama, as elsewhere, the agricultural labor is so scattering it does not strike. Strikes in other industries have been very rare in Alabama. There has been only one serious strike in the mill districts, and that was years ago. The question of compulsory arbitration has not been agitated. (925.)

Referring to the controversies between capital and labor, Mr. RICHARDS, a Chicago grain merchant, says wrong exists on both sides. As a remedy he proposes a national law authorizing labor organizations to be created, with as many subordinate classified branches as they may require, under a department of the Government. The present labor organizations have no legal entity. We have organized capital against disorganized labor; both should be on the same footing. (207, 208.)

3. Enticing laborers away.—Mr. HALE says Georgia has a law against enticing laborers away from their employment, but he does not think it amounts to very much. It was probably framed because of the traveling black missionaries who raised discontent among the hands with colonization schemes. There was a class of tramp negroes who were not industrious and found it easier to live by trying to move others than by doing anything themselves. Mr. Hale thinks in general that the law is not unjust and has accomplished some good. (379.)

4. The Southern attitude toward manual labor.—Mr. POOLE, of Alabama, says that among the old aristocracy of the South there was a tendency to look down upon the trades, but that is gradually disappearing and many of the best young men are going into trades. A neighbor of Mr. Poole's, who is a wealthy cotton mill owner, has a son at Lowell learning the textile industry. This is mentioned as one of numerous instances. Mr. Poole says there is in the South a very liberal disposition toward the mechanical trades. (921, 922.)

Dr. STUBBS says that not only is it respectable for white men to work with their hands in Louisiana, but some of the best and wealthiest men do so, and such labor is the admiration of everyone in that country. Dr. Stubbs has seen a millionaire's son plowing with a 4-mule plow.

Before the civil war there was no necessity for such labor, but there has always been a feeling among all Southern people that they should do the work when there was necessity. Even before the war Dr. Stubbs has seen the children of wealthy and aristocratic farmers who had gone to pieces financially take to hard work like negroes, and yet be received in the best society as always before. Dr. Stubbs remarks that a man who can make use of hired labor to do the work, whether he is from the

4. Improvidence.—Mr. POOLE, of Alabama, testifies that as a general thing the white farmers are more thrifty than the negroes. The negro share cropper, working 1 mule, will draw on account, perhaps, 100 or 150 bushels of corn for his family. If he wants a pound of coffee or a little sugar he will sell a bushel of corn to get it at a near-by country store, and generally by the 1st of March he is out of provisions and has to go to his landlord for them. The country merchant puts a very low price on the corn, but as soon as it is out of the hands of the negro it increases in value. The corn is generally bought by the smaller cross-roads storekeeper, while advances are generally furnished by the larger stores in the towns and villages. Mr. Poole says the merchant is human and gets all the profit he can, but there has been an improvement in this respect, and the condition of the negro has improved correspondingly. He thinks advances are furnished as reasonably as could be expected under the circumstances. The merchant takes a mortgage lien on the cropper's interest in the crop, frequently asking the landlord what amount he considers him good for, and holding him down to a certain amount until the crop shows what it is going to do. When the negroes make a settlement at the end of the year they go and buy whatever they want—furniture, guns, horses, wagons, buggies, etc., and generally get rid of their money very rapidly. If they were as economical as the whites they would own the Black Belt in a few years. (925, 926.)

Mr. HALE says it is the hardest thing in the world for a darkey to keep money. He urges his laborers to save part of their wages, and encourages them to buy household furniture or other staple necessities with it. In that way they are furnishing their houses a little better each year. They take fairly good care of their tenant houses, and were glad to paint them when he offered to furnish the paint. While entertaining a high opinion of the negroes as laborers, Mr. Hale admits that they are very careless about leaving their tools "anywhere and everywhere." (384.)

Dr. STUBBS says the Louisiana negroes do not want to spend any money on what might be called unessential improvements, and prefer natural luxuries to the artificial ones. (778.)

Mr. NUNNALLY remarks that when the slaves were freed they were thrown upon their own resources from a position in which they had been fed and clothed without care or forethought on their part. The negroes love a good time and are the happiest, most carefree people in the world; with plenty to eat and wear and a few dollars to spend at Christmas, they reach the height of their ambition. Not one in a thousand cares to provide for to-morrow, and but little progress has been made in accumulating wealth. Very few own homes of their own. (454, 455.)

C. Progress of the negroes.—1. *Intelligence and general condition.*—Mr. HALE thinks that around the large cities and towns where the negro has come into too close contact with the white folks, he has perhaps deteriorated, but in 10 years of agricultural work in the Black Belt of Georgia he has seen a very marked improvement in the intelligence, general appearance, and efficiency of the negroes. (400.)

Mr. POOLE testifies that the colored man in the Black Belt is well fed and clothed, law abiding, and well adapted to agriculture. The South seems to be his home. The colored people there come in contact with those who owned them when they were slaves, or their descendants. They are obedient and respectful, and there have never been any labor troubles. There is very little migratory labor in the Black Belt. (919.)

Mr. WHITE testifies that up to 1898 the condition of colored people in North Carolina was decidedly on the upper trend. The best feeling he had ever known in the South existed between the whites and colored people in that State. A large majority of the whites are kindly disposed to the colored man, as shown by their paying without a murmur the bulk of the school tax; but politics has made the situation bad for the negroes. (426.)

Intelligence and capability of negroes.—Mr. DILLINGHAM believes there is more intelligence in the American negroes than in any other black people in a civilized country. (167.)

Mr. HALE thinks the negro children are as bright as the average children of any nationality under similar conditions, and capable of a reasonable amount of education. (385.)

Mr. WHITE says that perfect equality of the two races, either in education, industry, or politics, is next to impossible. The white man's superior civilization for generations, and his supremacy, wealth, and education, will tend to keep the colored man his inferior; but the negroes and whites are dependent upon each other. (428.)

Mr. HAMMOND says that negroes with equal opportunities learn as readily as white people. His children have given lessons to the domestic servants, and have found

XXXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. KYLE, of Mississippi, thinks there has been a general advance of the negro race, but that they do not work as closely or as diligently as when they were slaves; yet he considers them the best labor the South has ever had. The great mass of them do not seem to have any ambition to own property, but occasionally they acquire farms and homes, and when they do they are very loath to mortgage them. Mr. Kyle thinks there is more hope for the negro in industrial education than in other lines. (467, 469, 471.)

Mr. HILL, of Memphis, while glad that the negroes are free, does not believe that they are improving. White people do not pay the same attention to the training of the negroes as they did in the days of slavery, when the children formed industrious and moral habits, and the negroes themselves do not control the children as well as the old slave parents did. The colored people will not live in the yards with the white people; they want to be by themselves. On Mr. Hill's plantation there are a few of the old slaves who are very well contented, but the younger ones are discontented and inclined to be idle; they work a few days and then enjoy themselves in the village until their money is gone. Mr. Hill says the colored man does not live as well as he did under slavery, and that it cost the slave owner more to support the negro than he now pays him under the wage system. (504, 505.)

Mr. MANSON, of Tennessee, says the negroes were taken a great deal better care of in slavery than they are now. If a negro got dangerously sick he was taken right into the house and cared for. On Mr. Manson's father's farm every negro with a family had a cotton patch of his own to buy Sunday clothes and extras with. They had plenty to eat and wear, and dressed better than they do now on Sunday. Mr. Manson agrees with Mr. Hill that their labor was dearer in those days than now; he thinks the greater cost was offset by the better control. (509.)

Mr. NALL, of Kentucky, says that when the colored laborers were slaves the master was expected to take care of them, especially when they were ill; and they were cared for as comfortably as could be. This was to the interest of the master. Now the colored laborers are congregated mostly in the outskirts of the towns. They sometimes suffer from diseases, and their personal physical condition is not so good as when they were slaves. They are subject to smallpox and other fatal diseases, and Mr. Nall thinks from observation that the rate of increase is less than formerly, yet he believes that a free man is better than a slave. (802.)

D. The negro as a farmer and as a workman.—1. Incompetence.—Mr. BROWN thinks that one of the great causes of agricultural depression in the South is the incompetence of the negro. The negro does not know how to use improved implements and does not want to know how. He is averse to raising anything except cotton. In fact the negro can not subsist by himself. He requires the direction and example of the white, and is much given to imitation. The witness cites the case of a certain territory which became exclusively inhabited by negroes, and which was finally abandoned for agricultural purposes. (62, 63.)

Mr. BARRETT thinks the negro is never a good farmer without white supervision; he can not be trusted to use improved implements; he is cruel and careless in his treatment of stock. (58, 59.)

2. Standard of living.—Mr. REDDING, director of the Georgia Experiment Station, thinks the great trouble with cotton farming in the South is that negroes, who are willing to live in the most primitive style on hog and hominy, can make cotton at 7 cents, though if they counted the labor of wife and children it would cost more than that. The white farmer is not willing to live so poorly, and must either make cotton at a less cost or get more for it, or he can not live. Mr. Redding thinks most of the farm tenants in Georgia are colored. (445.)

3. The negro's economic advantage in agriculture.—Mr. POOLE testifies that in his part of the Black Belt the lands are rented to negro tenants because they can afford to give more for them than the white man. Mr. Poole himself rents several plantations to the negroes because he can get more rent from them. The negroes furnish their own labor, and can afford to pay more rent than the white man who hires his labor. (926.)

4. Mechanical trades.—Mr. POOLE, of Alabama, says that before the war there were on every plantation two or three carpenters who had been taught the trade by their owners. While a number of these old carpenters are still living, they are diminishing in number, and their places are being generally supplied by white carpenters. (921.)

Mr. HALE thinks the negro rather predominates in bricklaying, carpentering, and blacksmithing in the small towns of the South. (401.)

Mr. REDDING, director of the Georgia Experiment Station, says that in the field of common labor the negro is a drag to white labor. Farmers can get negro hands for 50 or 60 cents a day, but Mr. Redding's observation is that skilled negro bricklayers receive about as much as white men. (445, 446.)

5. Negroes not generally employed in cotton mills.—Mr. WHITE says that, with an isolated exception now and then, the colored men are not allowed to work in the Southern cotton and woolen factories, and until recently the whites have had almost a monopoly of all skilled labor. The whites and negroes compete on the farm perhaps more than elsewhere. It is rare to find a white farm hand in eastern North Carolina; the white farmers either rent for themselves or have their own land. (429.)

Mr. HAMMOND, a cotton planter of South Carolina, says that so far colored labor has not been successfully utilized in cotton mills, though it was successfully used before the war, and though they now do other sorts of work, such as the running of gins, which are believed to require more mechanical ability than cotton-mill work. Mr. Hammond believes that there is no reason except race prejudice why the negro should not be put in cotton factories. He does not believe that their irregularity is a sound reason. He has tried both negro and white labor on the plantation, and he declares that the negro works better and more continuously than the white man and does not want so many holidays. (823.)

E. Education of the negroes.—1. *Discrimination against colored schools in certain States.*—*Maryland.*—Mr. AGER considers the school facilities for white children sufficient in Maryland, but says there is a lack of schools for colored children, many of whom are more anxious to get an education than the white children and go farther to get it. As a rule the white schools are looked after better than the colored. (106, 107.)

North Carolina.—Mr. WHITE testifies that there is more money paid to the white schools of North Carolina for a given number of pupils than for a like number of colored people. The teachers are paid more, though they may be examined by the same board and given the same certificate. He thinks the terms are longer in the white schools than in the colored. (424.)

South Carolina.—Mr. HAMMOND says the trustees in each school district in South Carolina have power to distribute the school funds according to their best judgment, and they generally pay higher salaries to the white teachers and give the white schools a longer term. The white teachers get from \$40 to \$45 a month, and the colored teachers \$30, yet in Mr. Hammond's district the white schools have an enrollment of about 35 or 40 pupils, and the negro schools about 200. The negro children are very irregular in their attendance. The desks and seats in the white schoolhouses are made by local carpenters out of pine after the model of the improved school bench. Each pupil has a seat to himself. Mr. Hammond thinks that in the colored schools there are only benches. (824-826.)

Georgia.—Mr. REDDING says the negro schools of Georgia generally have negro teachers, who are not as well paid as the whites. He supposes that very few of the teachers are paid as much as \$40 a month. The pay is regulated by the county board. He thinks the school accommodations for colored children are not quite as good as for the whites, but sufficient facilities are furnished. There is no difficulty about schoolhouses, a few men get together and put up a house in a day or two that answers all purposes for an ordinary school. (451, 452.)

2. Equal school facilities in certain States.—*West Virginia.*—Mr. CLOHAN testifies that the course of study and the school term are the same in the colored and white schools of West Virginia, and that the colored teachers have to pass a pretty rigid examination and are well qualified. Most of the colored teachers are men, though in the white schools the proportion of female teachers is 4 to 1. There are many colored children who have to travel 3 and 4 miles to get to school, on account of the sparse population. In some magisterial districts there is only 1 colored schoolhouse, and some districts have no colored school at all, the children attending a school in the neighboring district. (594.)

Kentucky.—Mr. NALL testifies that in the agricultural part of Kentucky the farmers were largely slave owners, and there was some prejudice against improving the negro race; but he thinks that has all died out, and for several years Kentucky has had more liberal educational laws. White and black now have equal school facilities. All taxes for school purposes go into a common fund, and the money is drawn per capita, the colored pupils getting the same as the white. Mr. Nall thinks that up to the high school the colored schools are as good as the white, being taught by very efficient colored teachers. In the days of slavery it was forbidden that the negroes should be taught, and it was rare to find one who could read. The colored people are still separated from the whites as much as possible in social relations. There are separate coaches on the railroads for them, but the carriers are required to furnish equal accommodations for the money paid. (803, 814.)

Tennessee.—Mr. MANSON, of Saulsbury, Tenn., says the school facilities in his region are just the same for white and colored (usually 2 months in the winter and 2 in the summer), but the negroes do not take much interest in school. When a boy gets to

XXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

be 14 or 15 years old and does not want to go to school his parents do not make him go. (507, 508.)

Mr. HILL testifies that 90 per cent of the school taxes of Memphis are paid by white people, although the negro population of school age exceeds the white population of school age by 1,200. (504.)

Alabama.—Mr. POOLE testifies that the school facilities of Alabama for both whites and blacks are very much improved, though not yet what they should be. The same amount is given for the same number of days of schooling in white and colored schools. The school term has been increased equally for the colored and for the white pupils, but frequently the schools are continued by private subscriptions. A compulsory education bill was introduced in the last legislature, but failed of passage. (923.)

Mississippi.—Mr. KYLE testifies that there is no distinction between the races in the matter of school facilities in Mississippi, except that the colored teachers do not generally hold as high grade certificates as the whites, and their salaries, being based on the grade of the certificate, are not as high. The negro children generally attend pretty regularly; they are anxious for an education, though Mr. Kyle thinks no more so than the poor whites. There is no discrimination between the races in the length of the school term. (468.)

Louisiana.—Dr. STUBBS says there is a preponderance of colored schools in Louisiana. Although the taxes collected from the colored people amount to very little, the school fund is divided pro rata according to the number of children. The State also appropriates annually a large amount toward the maintenance of an agricultural and mechanical college for the colored people and a considerable amount for a colored normal school. The negroes are a very heavy tax on the whites, constituting a very large part of the population and paying no taxes to speak of. Not only must they be educated, but the court costs, jail costs, etc., amount to a very large sum. (779.)

Arkansas.—Mr. BALCH says Arkansas has the same school facilities for the negroes as for the whites. The teachers are paid according to the certificate they get, but a great many colored teachers have first-grade certificates. Most of the negroes are very anxious to send their children to school, but a few of the ex-slaves disapprove of educating a laboring man. (497.)

3. School attendance.—*North Carolina.*—Mr. GRAHAM says the school attendance of negroes in North Carolina is greater than among the whites. He attributes this more to the fondness of the negroes for getting together in any kind of a meeting than to their desire for education. (439.)

Georgia.—Mr. NUNNALLY testifies that the negroes of Georgia take advantage of the schools up to 18 years of age, and that nearly all the children are learning to read and write. (456.)

Mr. PEEK testifies that the negro will go to school every day he has an opportunity, and in Georgia he has the same opportunity as the whites. (459.)

Alabama.—Mr. DILLINGHAM testifies that the negroes of Alabama show a disposition to learn. There are boys at the Calhoun School who walk 8 miles a day to attend school. (167.)

Tennessee.—Mr. GODWIN says colored schools are provided in Tennessee, but he does not see much interest taken in them. He does not think that children from more than 3 or 4 families out of the 15 or 18 families on his place attend school at any time during the year. (476.)

4. Higher education.—*North Carolina.*—Mr. WHITE speaks of a surplus of colored teachers in North Carolina, the facilities for higher education of the colored people being very good. Four additional normal schools have been created, and there are now 6, 7, or perhaps 8 colored normal schools, besides a great many denominational institutions, such as Bennett Seminary, at Greensboro; Scotia Seminary, at Concord, maintained by Northern people largely, where the president and the majority of the teachers are white; Livingston College, at Salisbury; Shaw University and St. Augustine Normal and Industrial Institute, at Raleigh; and the Gregory Normal Institute, at Wilmington. The endowments are not sufficient, and the institutions have to keep financial agents on the road begging all the time. The students, as a rule, pay their own way; now and then a philanthropic person in the North gives a scholarship. (425, 426.)

Tennessee.—Mr. MANSON testifies that Fisk University, at Nashville, for the higher education of negroes, is supported in part by the State of Tennessee. (509.)

Mississippi.—Mr. KYLE says there is a State university for the colored people at Rodney, Miss. Shaw University, at Holly Springs, built by the contributions of charitable Northern people, has received annual appropriations from the State treasury. There is also a school for colored girls, supported by Northern people, and a well-attended agricultural and mechanical college at Starkville. (403, 469.)

5. Professional education and occupations.—Mr. KYLE, of Mississippi, thinks the negroes who attend the universities do not, as a rule, take professional courses after completing the college curriculum. There are few colored doctors. Mr. Kyle has lived in a town where there were 2 or 3 colored lawyers and at least 1 colored physician, but they were not patronized much by the colored people. (469.)

Mr. STEVENS says the educated negroes very often become teachers, preachers, and professional men. Some of them branch off into merchandise and do well, while others fail. Very few of the educated ones remain on the farm. (910.)

Mr. POOLE says that in the rural districts of Alabama there are generally colored teachers for the colored schools and white teachers for the white children. At the Patterson School, a State normal school for colored teachers, with an attendance of 750, there are both white and colored teachers. (923.)

6. Is negro education useless or detrimental?—Mr. YOUNG, of South Carolina, is disposed to be friendly toward the negroes and cheerfully pays taxes for their education, but thinks the money is thrown away. He thinks education is of no benefit to the negroes, his experience indicating that the educated negro is of no account, and that education does not improve his morals. (119, 120.)

Mr. MANSON, of Tennessee, believes that farming is the natural vocation of 19 out of 20 negroes, but says that as soon as a negro can read and write and cipher a little he does not want to work on a farm any longer. He says 75 or 80 per cent of the negroes in the Georgia penitentiary can read and write, a much larger proportion than among the negroes outside of the penitentiary. Education does not elevate the negroes morally. (508, 509.)

Mr. HAMMOND, a cotton planter of South Carolina, does not think that education spoils the colored child. He is as faithful after getting an education as before. The white people of South Carolina generally favor the education of negroes. (826, 827.)

Mr. DILLINGHAM says the condition of things in the black belt is dangerous and urgent; at the same time the situation is hopeful if reasonable stimulus, help, and guidance can be given the colored people. The nation can have there a body of intelligent, taxpaying, industrious, thrifty citizens if it pleases. (164.)

7. Desirability of agricultural training.—Dr. CROWELL, formerly president of Trinity College, North Carolina, says that an education that is not disciplinary would not be of much value to colored people, and that an education not primarily agricultural would detract from their usefulness in agriculture; it would probably cause them to leave the farm. The educational scheme should deal first with the three R's, and secondly with plants, soil, atmosphere, etc. (336.)

Mr. DILLINGHAM believes that the nation and the States should do something to teach colored men to be farmers. (166.)

Mr. NALL, Commissioner of Agriculture of Kentucky, has great sympathy with the negro and is willing to do everything he can to elevate him. If he finds a community of negroes trying to farm and be independent he is going to hold institutes among them and do what he can to improve their condition. (815.)

F. Proposed solutions of the negro problem.—**1. Negro communities in the South.**—Dr. CROWELL looks with much favor upon the tendency among industrially educated negroes to establish themselves in colonies on small farms, but predicts that the tendency will be checked if the Southern States fail to give the children proper educational privileges in the locality. He says the most ambitious character in the South to-day is among the colored people. (335, 336.)

Mr. STEVENS does not believe that village communities of negroes would be an advantage. There is no part of Georgia except in the mountainous country (where there are almost no negroes) in which there is not within a radius of 3 miles a sufficient number of children between the ages of 6 and 18 to form schools and churches. Mr. Stevens does not believe it would be an improvement to collect them all together. They do better where they are separated. (906.)

Mr. NALL suggests that people be encouraged to improve the villages of the laboring men and make them more attractive. The people of Kentucky can not go ahead and do what they would if the laborers were white, because the colored laborer when he gets money and accumulates property feels just like one of the whites, and it is impossible for those who have known the negroes as slaves to recognize an equal social position for them. In sparsely settled parts of the country, therefore, where there are not enough of them to make a village of their own, the white people can not take them in and make them a part of the community as they could if they were white people, even of little education. (815.)

2. Colonization.—Mr. BROWN thinks that the only solution of the difficulty is the separation of the races. The Fitzgerald settlement in Georgia was started by whites with the purpose of excluding negroes altogether from a certain territory. The inhabitants seem well satisfied with the experiment, and their town is prospering.

The witness advocates the attempt to colonize the negroes either in some part of this country or elsewhere, and would approve of an appropriation by Congress for that purpose. It is doubtful, however, whether the scheme is practicable. The negroes themselves probably do not want to go. The whites of the South are so dependent upon negro labor that they would at first object to sending it away, but in the long run it would be better for them, even if lands lay idle for some time before laborers could be found to work them. (62, 63.)

Mr. YOUNG is opposed to sending the negroes out of the country and colonizing them. Although the negro makes way with whatever he earns, he thinks there is good in him. The sections in which there are only white people do not look any more prosperous than those in which there are negroes. (120.)

Mr. DUNCAN, of South Carolina, states that there is certainly a surplus of negroes in certain parts of that State, and that it would perhaps be well to send out a colony of the surplusage; but he agrees with Colonel Orr (See Vol. VII, pp. 485) in his opposition to sending the negroes as a body out of the country. He thinks the negro is a necessity in the South as a farm laborer. (518.)

Mr. WHITE is decidedly opposed to the colonization of negroes, either within or without the United States. The negroes have copied the civilization of the white man. Mr. White suggests that Bishop Turner, with whom colonization is a hobby, has an underlying purpose to accomplish. He knows his white neighbors do not care to have the negroes leave, and his purpose may be to arouse them to mete out justice in order to keep them. (428.)

Mr. POOLE, of Alabama, believes the attempts which have been made to carry off the colored people from Alabama and colonize them elsewhere were money-making schemes, and not for the benefit of the negroes as a whole. Mr. Poole does not think the colored population of the State would be better off in any other State in the South. He thinks 99 per cent of the white people of Alabama are glad to have the negroes there. They are comparatively law abiding. "They will steal a little bit sometimes, but they make good farm laborers and good servants generally." (924.)

3. Emigration of negroes from the South.—Mr. WHITE is in favor of relieving the overcrowded agricultural communities of the South by a gradual thinning out of the negroes, taking them here and there among the white people of the East, West, and North, where they may have a new impetus by the changed habits and opportunities and educational facilities. Where his white neighbors are poor and illiterate the negro has nothing to aspire to, and he goes from bad to worse; but where there is a higher ideal he will advance.

Mr. White says the mortality among the negroes who went north after the war was very great. A colored man past middle age going North will probably contract some pulmonary trouble, but the younger negroes become acclimated, and the children of those who went North after the war are not affected. Mr. White has found a great many negroes in Massachusetts, Maine, and the Northwest who were healthy, robust and thrifty. (428, 429.)

4. Further investigation needed.—Mr. DILLINGHAM, principal of the Calhoun Colored School, Alabama, says he feels deeply the fact that though a generation has passed since the colored people were emancipated, practically nothing has been done by the Government in the way of careful inquiry into the conditions of these new citizens. He suggests that if the Industrial Commission were to investigate conditions of agricultural labor in the Black Belt it would have a value difficult to estimate, and would show the urgency of the situation and the nation's responsibility. He suggests that carefully selected typical areas be chosen in different sections of the cotton belt and investigated, with cooperation with such schools as Hampton and Tuskegee and such settlements as that of Calhoun. Expert supervision would be necessary. An expert should prepare a catechism for the inquiry and take a certain amount of testimony himself on the spot. There is great need for the collection of statistics. The study should also include the white tenant. (163, 164, 167.)

G. Character of foreigners as farmers.—Mr. POWERS, of the Census Office, testifies that the foreigners on the farms of this country are largely men who were employed in Europe as agricultural laborers. He does not remember ever meeting a man on a farm who came from a city. These foreigners have come largely from Germany, Scandinavia, and Great Britain. A few from Bohemia have settled in certain sections, and many of the best educated among the Irish immigrants have gone onto farms. The percentage of literacy among the immigrants who have settled on farms is probably not far from that of the people of the North as a whole. The immigration from Scandinavia probably has a larger percentage of people who can read and write their language than the native population of almost any State in the Union. The percentage of literacy among the Germans is a little less. The Irish, when they come to this country, represent a still lower degree of average

education. Mr. Powers thinks that the general intelligence of foreign immigrants has been such as to elevate the general character of Western and Northern agriculture. The more educated foreigners, up to a certain level, go to the farms. There is a certain ignorant class among the Irish that drifts into the cities. When Mr. Powers has met the Irish in the country he has looked upon them as most desirable people. He never saw on the farms of New York any of the drinking element to be found in cities.

Mr. Powers says the first great motive of immigration is to obtain a home. Both foreign immigrants and native Americans went West before there were markets there, but the creation of markets has greatly stimulated the movement, and men now get homes mainly where markets have been provided by the building of railroads.

Mr. Powers states, as the result of an investigation he made while Commissioner of Labor of Minnesota, that the American-born farmer is able to make a slightly greater progress in the accumulation of wealth than the foreign born. He says it takes a man some time to adapt himself to changed conditions. (179, 180.)

Professor DAVENPORT says the better class of foreigners who have gone onto Western lands have succeeded and become wealthy. The Scandinavians and Germans are ambitious for land and money. Farmers from Europe have a higher idea of the value of fertility of land than Americans have. (263.)

Mr. STOCKWELL refers to a lecture by President Pritchett, of the Massachusetts Institute of Technology, before the winter meeting of the Massachusetts Board of Agriculture, which showed that our early immigration was English, Irish, Scotch, and German, a valuable addition to intelligent citizenship, while now the immigrants are Poles, Italians, Finns, and others of the less intelligent races. These immigrants are drawn more largely into other pursuits than into agriculture, however. (884, 886.)

Mr. Stockwell says the cheapest labor in Europe and Asia is now brought to this country for the benefit of mining and railroad corporations. The influx is not as great as a few years ago, so we are reaching after cheap labor from the islands of the sea. The cheaper the help the more they are sought for by the great corporations. This is a part of the commercialism of to-day. (886, 887.)

New England.—Professor DAVENPORT predicts that the foreigners who are taking up abandoned farms in New England will succeed, because (1) their cost of living is comparatively low, and (2) they know the necessity of keeping up the fertility of the soil. (263.)

Mr. SPEAR says the immigrants coming to Vermont as farm laborers are principally Canadians and Scandinavians. The Swedes and Norwegians are the best help; Poles are also very satisfactory. In a good many cases the Scandinavian immigrants become landholders and permanent residents and make good citizens. They sacrifice social advantages and take farms remote from schools, post-offices, and railroads, which are obtainable for very small prices. There is no marked tendency to colonize or to preserve foreign customs. The immigrants are mostly young men, though some have families who follow later. Scandinavians are also being employed as domestics more than formerly. (402-404.)

Mr. STOCKWELL, of Massachusetts, says the immigrant class takes the first labor at hand, which is usually manufacturing or laborer's work. If the corporations evade the law and bring over immigrants for a low price to do a certain kind of work, that is their first work; but as they leave it they drift into other lines, including farming. Some of them make very good farmers. The Swedes are a very good class of workers and citizens, and some of the Poles have done very well. The Italians are seldom seen on farms in Massachusetts, though they are good workers in other lines. (886.)

New York.—Mr. NORRIS, of Sodus, N. Y., says Germans and Hollanders predominate among the foreigners in that part of the State. The Germans as a rule are quite intelligent, and have had educational advantages, more so than the Hollanders. Foreigners control most of the land of Wayne County; they seem to be born agriculturists and they make good citizens. If one of them goes to a farmer, and stays with him about 10 years, he generally buys the farm and the farmer moves to town. They are better farmers and more thorough in tilling the soil than the Americans. The Hollanders, especially, pick up lowlands, ditch them out and reclaim them, and raise large quantities of onions, celery, etc. (323.)

Mr. Norris says there are hardly any Italians in his part of New York, but he is told that near Rome, where sugar beets are largely grown, Italians living along the canal to work on the canal and railroads are employed, together with the women and children, to weed out the beets. (323, 324.)

New Jersey.—Mr. DYE says the early German and Swedish immigrants who went upon the farms in New Jersey were thrifty and industrious. There are still

opportunities for foreigners to come and establish little homes of their own, especially because of the low price of lands. It would be of great advantage to many of them to enter farming and stick to it rather than to seek employment in the crowded cities. A large proportion of the immigrants who are now coming upon the farms come as transient laborers. The farmer has to teach them their business, usually, and no sooner have they become somewhat efficient than they quit farming. To some extent, however, Hungarians, Swedes, Germans, Italians, and Jews are taking up market gardening and fruit raising independently. They improve as they settle permanently and mingle with native people, although there is some tendency among them to form colonies. Many pieces of land which were considered barren a few years ago are being utilized by such immigrants. (85, 86.)

Mr. COLES testifies that some immigrants are settling in southern New Jersey, but they are usually members of families who are already there. There are a great many native-born citizens of foreign parentage who are very good farmers, economical in their habits, and generally very successful. They are mainly Germans and Irish; there are also several Jewish colonies. Some of the German women work on the farms, and some few of the Irish women. Children of immigrants are purchasing farms to some extent, and some of them occupy farms formerly occupied by Americans. (124.)

Ohio.—Mr. BRIGHAM says there are many sections of Ohio where Germans and French are numerous, although in the particular section where the witness lives the farmers are mostly native. There is a tendency among the foreigners to form colonies, and even to insist on their own language being taught in the schools, but the majority of them are growing away from this practice. (10.)

Michigan and Indiana.—Mr. AARON JONES regards the Swedes, Germans, and Hollanders on the farms of Michigan and Indiana as thoroughly desirable citizens, although they have a tendency to form colonies. The Hollanders are reclaiming the lowlands and making good farms of them. There are also many Poles, and native farmers find it impossible to compete with them in the local markets. They keep up parochial schools. (34.)

Illinois.—Professor DAVENPORT says a great many of the unmarried men employed on farms in Illinois are foreign born, especially German and Scandinavian. They are not, as a rule, from southern Europe. (256.)

Mr. WILSON, master of the Illinois State Grange, says the Germans of Illinois are good farmers. Many of them get more help from the women and children than the Americans do, but otherwise do not raise crops any more cheaply. It costs some of them as much to live as it does the Americans, but others live more plainly and use coarser food, without variety. Their manner of living may depress the local markets somewhat. (246.)

Minnesota.—Mr. HANLEY says there are a great many Scandinavians, Germans, and Irish among the farmers in Minnesota. They work hard and are successful. Where they form colonies they do not become Americanized as rapidly as elsewhere; there are some sections where they can not understand English. (277.)

North Dakota.—Mr. BUDGE testifies that North Dakota is being rapidly settled and developed. The growth is now taking place most rapidly in the central portion of the State, where a rich farming area is being opened. The branch railroads are pushing out into a territory previously unoccupied. An increase of more than 74 per cent in population during the past decade is a growth equalled by but very few States or Territories. The settlers are usually of an excellent character—industrious, and, for the most part, intelligent. Many were farmers in other parts of the country or in Canada. They are rapidly improving their farms, and many who have been in the State a few years possess respectable bank accounts. Towns are putting in electric-light plants and waterworks; public buildings are being erected, and the schools are well supported. Mr. Budge refers to a wonderful increase in the numbers attending the public schools and institutions of higher education. (845, 846.)

Mr. Budge says the immigration to North Dakota comes from Norway, Sweden, and Germany. There are also a few Hollanders, Russians, Scotch, Irish, English, Canadians, and Poles. The remainder come from the States. There are French Canadians in Walsh County, and a few in Cass County. (847.)

Mr. PROM says the population of North Dakota is made up mainly of Scandinavians and Canadians, with some French. They are desirable citizens, except where the French colonize in villages or mix with half-breeds. The village of Olga, north of Milton, is an Arcadian village, where they preserve their customs, speak French exclusively, and have French priests. (788, 789.)

Mr. PROM says the Scandinavians and Canadians work well together in North Dakota. They are generally industrious, and have aided materially in developing the country. In the neighborhood of Milton the Scandinavians predominate, mainly

Norwegians. The Icelanders came first to the neighborhood, then the Norwegians, then the Canadians. The proportion of Americans on the farms is hardly noticeable.

The Canadians come from Ontario. The migratory population which returns to Canada in the winter is not large, probably not 10 per cent of the whole. It is composed mainly of young unmarried men. When they can afford to do so, they marry and settle down in the State and become citizens of the United States.

Mr. Prom thinks that special inducements have been offered by railroad corporations to bring immigrants to the western part of North Dakota. (789.)

South Dakota.—Mr. M. F. GREELEY, of South Dakota, says that most of the hired help in that section are foreigners, and a great many of Mr. Greeley's neighbors are Scandinavians and Germans. In his farmers' institute work in Minnesota Mr. Greeley has found the Scandinavians, Germans, and Canadians the most intelligent, practical, and thorough farmers in the older sections, where they have had opportunity to become thoroughly Americanized. They are almost invariably prosperous after they get acquainted with the country, language, and customs, and, with scarcely an exception among those Mr. Greeley has come in contact with, become landowners. They seem to realize what it means to be without a piece of land in an overcrowded country, and seem determined not to be caught without land a second time. A larger percentage take lands than among the native Americans. The American boys, as a rule, seem to think they can get land at any time, but the foreigner sees plainly that it is going. It is hard to get an American boy to become interested in land. Mr. Greeley predicts that American boys will be the hired men and tenants of foreign landowners in the near future. Yet, he says, there is an increased tendency, particularly among the Minnesota farmers and their sons, to stick to the soil. (929, 930.)

Mr. Greeley remarks that foreign farm laborers seem to be more thorough than native Americans. They seem to expect to do something for what they get, and to do it as it ought to be done. They have made a business of mastering some kind of work and are proud of it. If a farmer wants a good shepherd in South Dakota he generally tries to get a Scotchman or an Englishman. (928.)

Mr. Greeley declares that the people who have come to this country from Scandinavia, Germany, and Canada have greatly helped the agriculture of the Northwest. To take them out of some sections would nearly ruin the country. Mr. Greeley considers the Americanized Scandinavian the best citizen in the Northwest. (930.)

Southern States.—Mr. BARRITT says there is little if any immigration into the Southern States. The cost of negro labor is so low that no other class can compete. Moreover, white men will not work beside negroes, and unless immigrants should form colonies they would largely be forced to associate with negroes. A few immigrants come to take employment in the new cotton factories. (46, 52.)

Mr. HALE also says there is practically no immigration in the South. (382.)

Mr. AGER testifies that there are few immigrants in Maryland, and they are mostly Germans, who are generally thrifty, industrious, and good citizens. He has known them to go to work as farm laborers and in a few years have lands of their own. He thinks their presence has improved the condition of agriculture. They generally settle near the cities and engage in truck farming, which requires less capital than general farming. Mr. Ager thinks there is a grand opening for foreign immigrants in portions of the North and West and in Maryland. There is very fine land between Washington and Baltimore which needs only intelligent cultivation. (106.)

Mr. NALL says there is a drift of thrifty Germans around every city in Kentucky. As a class they work their own farms. (803.)

Mr. PEEK says there are one or two colonies of foreigners in Georgia, but no immigration from the Northern States to amount to anything. (460.)

Mr. STEVENS says there is very little foreign immigration of any kind in Georgia, most of the newcomers being Americans from the North and Northwest, and from the Southern States. This class of immigrants make the most satisfactory citizens. The few foreigners in Georgia are compelled by their surroundings to become Americans, adopting the English language and conforming to American customs.

Among the most thrifty, prosperous, and best citizens of the State are some Germans near Savannah. They are producing large quantities of vegetables, have gone into the dairy business, and are developing the country to a wonderful extent. They do well, and have given the other residents some new ideas. The people of Georgia are not seeking to have common laborers come into the State; what they would like would be to have people come there and settle on the land, help develop the resources of the State, and become citizens. The Southern people are intensely American and cling to American ideas, but they are not unfavorable to the best class of foreigners, some of whom are among their best citizens. (912, 913.)

Mr. Stevens calls attention to the recent landing of a number of immigrants at

XXLIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

New Orleans, mostly Italians and Hungarians, who are to work, he is informed, in the sugar-cane fields of Louisiana. A few have been secured to work in the coal mines near Birmingham, Ala. (912.)

Mr. POOLE says there is very little immigration of white farmers or foreigners into Alabama. (927.)

Mr. KYLE says the Italians in Mississippi are very successful cotton farmers. They are more energetic and more successful than the negroes. The Italian, however, does not stay long on the fertile lands; he stays until he has enough money to engage in some other business and then drifts back to the city. He is, therefore, not as desirable a laborer as the colored man, who stays on the farm. (467, 468.)

Dr. STUBBS testifies that between 25,000 and 30,000 Italians have been imported into Louisiana in 15 years. There are also some Germans and Swedes. As between the Italians and the negroes, some of the planters prefer one and some the other. Those who have stores prefer the negro, because he will spend 95 cents out of every dollar he gets, while the Italian keeps everything he can get. The French immigration is of a rather higher order. (777.)

New Mexico.—Mr. WHITNEY mentions a settlement in the Pecos Valley of New Mexico where a large area of land was taken up and put under irrigation. Agents were sent from this country to attract immigration, and settlers were brought from Switzerland, France, and Germany to introduce European grapes, develop the sugar-beet industry, and grow fruits and truck crops. The scheme failed completely because the soils, water, and climate were not suited to the industries that were started. The water is very alkaline. The failure was due also to the unfamiliarity of the people with the conditions. (860, 861.)

California.—Mr. TURNBULL regards the Chinese as undesirable inhabitants. They wear their own dress instead of adopting ours. They do not seem to adapt themselves to the customs of the country. By reason of their gambling and from other causes, the 35,000 Chinamen in San Francisco give the police more trouble than all the rest of the population. It is almost dangerous to go through Chinatown in the daytime without being well armed or accompanied by a policeman. (976, 978.)

Mr. Turnbull says, however, that the Chinese can learn very readily if they have the opportunity. They are brighter than the Japanese. The skilled Chinaman is as bright as any man. They are also very steady and punctual, and stick close to their work. They surpass many white men in these ways. In some degree and in some classes of work they may be preferred to white men on this account, but in general they are not. A white man commands higher wages than a Chinaman in California for the same kind of work. Mr. Turnbull places the difference at 50 to 75 cents a day. Skilled Chinese workmen are employed in sundry trades, tailoring and shoemaking, and various manufacturing establishments, which they maintain in a small way. Chinese labor is employed on the farms, especially in the fruit-picking time, and in the sugar-beet industry. They are on the railroads as section hands and in construction work. (976, 978.)

Mr. Turnbull states that Chinese women are brought to California and sold and kept in a kind of slavery for purposes of prostitution. The Chinese merchant is entitled to bring his wife. He may bring one of these women and sell her; that is one way that they get in. The practice has existed for at least 10 years. The United States authorities have recently taken hold of the evil, and it is hoped that it will be suppressed. (978.)

Mr. NAFTZGER testifies that Chinamen have in many cases become owners of fruit orchards, and are industrious and frugal; but they live alone, without any family relations. In a few instances only have Chinamen married and become permanent settlers, and they are all in the cities. (955.)

Mr. Naftzger says many people in California prefer Chinamen as domestics, because the Chinaman, as a rule, will do more than any woman, and does not object to any part of the work. He is usually faithful, and seldom cares to run about much. Chinese domestics get from \$1 to \$1.25 a day, or from \$30 to \$35 and \$40 a month. (955.)

Mr. Naftzger testifies that the Chinese and Japanese in California have no social status whatever; they are not regarded differently from the Indians or Mexicans in that particular. Mr. Naftzger has never observed that they show any desire to be treated as social equals. (954.)

Mr. Naftzger thinks Japanese labor is in less favor for common work than Chinese. The Japanese want house places and light jobs, though some of them do such work as fruit picking and packing. They want to live in a little better style than the Chinese, and are more particular about the class of work they do. They dress exactly like Americans, and adopt American habits more than the Chinese. Many

of the Chinamen also wear American clothes, doubling their queues up under their hats. Few Chinese and Japanese are born in this country. (967.)

Mr. Naftzger testifies that the Mexicans in California are chronically indolent, and will not work as long as their stomachs are full. The Spaniard is a somewhat different type. (957.)

H. Colonization of foreigners.—1. Preservation of foreign customs and languages.—Mr. STOCKWELL, of Massachusetts, says the Italians are very much inclined to congregate together. He does not think that tendency general among the immigrants in Massachusetts, however. The children attend the schools, learn English, and desire to associate with the children of the natives. The French Canadians become naturalized very soon after arrival, and take an active part in public affairs. The number of immigrants is not sufficient to furnish any opportunity for them to do otherwise than go into the public schools, except the parochial schools, over which there is a certain oversight. (886.)

Mr. NORRIS, of New York, says Hollanders especially are quite clannish, a little more so than the Germans. There is a tendency for them to settle in little neighborhoods. Lyons, the county seat of Wayne County, N. Y., is controlled, politically and otherwise, by the Germans. (323.)

Mr. WILSON, master of the Illinois State Grange, says there is a tendency among the foreigners in Illinois to congregate in colonies. They do not become Americanized as quickly as where they are distributed among the native born. (246.)

Mr. POWERS says colonies of Germans in the Northwest, especially when settled under semireligious auspices, maintain the foreign language; while Scandinavians seek to put their language behind them. Some of the German colonies insist upon devoting a part of the day in the public schools to the study of the German language. (180.)

Mr. M. F. GREELEY, of South Dakota, says there are in the Northwest communities of foreigners who are inclined to colonize and preserve their language and habits, but the better class of foreigners prefer to be blended with the Americans, which is a mutual benefit. The colonizing is bad for the immigrants and for the country. (930.)

Mr. BUDGE says there is not much tendency on the part of the immigrants in North Dakota to colonize to preserve their language. The Scandinavians have tried to build a Scandinavian school, but the boys all go to the university, where one-third of the students are now Scandinavians. There is a chair of Scandinavian at the university, but the Scandinavian boy very seldom studies Scandinavian, though some Americans do. English is the language taught in all the common schools. (347.)

2. Beneficial results of colonization.—Dr. CROWELL says a large part of our agricultural labor has come from colonization. The colonies have taken up tracts of land, selected by carefully chosen agents, as a rule, and thereby laid the foundation of economic prosperity. They preserve their agricultural instincts and abilities on a much higher level than the American farmer who has moved West. The Pennsylvania Dutch, the best farmers in the United States, have maintained their industrial enterprises amidst all changes, so as to increase their wealth and keep up their standards, while other sections of the country have lost ground. They have always been able to make good profits out of the land, although the price of land in Lancaster County is high. (333.)

Dr. Crowell attributes the success of the Pennsylvania Dutch as farmers largely to the fact that they have not taken part in the general tendency to waste their resources in luxuries. They put their surplus into their farms or into the education of their children. They sow such crops as succeed each other in the course of a year, so that no crop suffers for lack of attention when it is ready for harvest. (334.)

Dr. Crowell calls attention to the same strong colonial solidarity and fidelity to the interests of agriculture among the Scandinavians in Minnesota and the West. The farm unit is the life, center, and soul of the community. He attributes the high level of agriculture in the Northwest and the prosperity of these farmers to the prevalence of that colonial solidarity which resists any tendency to impair economic efficiency. He also mentions the Huguenot colony of North Carolina, which is making itself felt in the same manner. This colony brought its standards of agricultural energy from the valleys of the Alps. These foreign colonies, he says, have been the mainstay and bulwark of progressive agriculture. The Scandinavian farmer has had centuries of training in the effort to make a dollar go as far as possible, as he had to do on his little patch of land in Scandinavia, and that he is more given to continuous labor than the American farmer. Dr. Crowell counts the economic traditions of the European farmer as among the most valuable assets of American agriculture. (334, 335.)

Dr. Crowell says technical education amounts to practically nothing as far as the

Pennsylvania Germans are concerned. He has understood that the Scandinavians in the Northwest are very much more apt to avail themselves of such advantages; yet the German colony in Pennsylvania is more advanced in agriculture because it is nearer large markets and responds readily to the demands of the market. (337.)

3. Assisted colonisation.—Mr. DYE says there are in New Jersey, especially in the southern part of the State, a number of colonies of Jews which have often been aided by philanthropic effort. They are mostly occupied in agriculture. A man will be given perhaps 10 acres of ground, a little house built for him, and he will be aided and instructed in raising certain crops, with the understanding that if he is industrious the property can be made his at a low price in the future. Each of these settlements occupies perhaps several hundred acres, the aggregate amounting to thousands of acres. Their progress has been slow, but on the whole they are succeeding very well, although the possibility of securing outside aid has some tendency to foster indolence. The system, in Mr. Dye's opinion, is of doubtful benefit to the country. (85, 86.)

1. Encouragement and restriction of immigration.—**1. Restriction advocated.**—Mr. BRIGHAM, Assistant Secretary of Agriculture, is inclined to believe that this country has been too generous with its public lands and other inducements for foreign immigration. The competition of the new lands opened up by them has been a serious injury. The railways and steamship companies have advertised these free lands and used other inducements. The witness would not favor excluding immigrants who are likely to become good citizens, but believes in tests as to their intelligence and moral character. He admits that the immigrants who go on farms are mostly of a relatively high class. (10, 11.)

Mr. DYE, of New Jersey, also believes that this country has offered undue inducements to immigrants, the public-land policy especially having been too generous. Railway and steamship companies have advertised public lands and encouraged immigration. For the present immigration should be greatly restricted, educational and property tests both being applied. If this were done the labor problem would soon settle itself. (86, 87.)

Mr. POWERS suggests the restriction of immigration on the basis of education and moral character. (182.)

2. Encouragement of desirable immigration suggested.—Mr. NORRIS would rather encourage than discourage the immigration of the classes of foreigners that have settled in New York State. (323.)

3. Chinese exclusion act.—Mr. NAFTZGER thinks the people of California, even including the fruit growers, (see III F 1) generally favor the extension of the Chinese exclusion act. It is regarded as a safety valve. They have no disposition to force out of the country those who are here, who are a peaceable people and seldom disturb public order; but they have no desire for an increase of the Chinese population. (954, 955.)

Mr. TURNBULL says that if the Chinese exclusion law is not renewed the white labor of the Pacific coast will come into competition with the labor of 600,000,000 Chinamen. The cheapness of the Chinese labor already in California is such as to shut out the unskilled labor of white men. The people of California are overwhelmingly in favor of the continuation of the exclusion law. No man could be elected to office on any ticket if he opposed it. (976, 977, 979.)

4. Distribution of immigrants.—Mr. M. F. GREELEY thinks the distribution of immigrants, if it could be made rather general so as not to colonize them, would be a benefit both to the country and to the immigrants. He does not think there would be any difficulty in placing the immigrants that would be brought into the farming districts of the West. Any sober, land-loving man, with a little experience in farming or stock raising, would have no difficulty at present in working into steady employment. (930.)

V. THE MOVEMENT TO THE CITIES AND THE WEST.

A. Abandoned farms in Eastern States.—**1. Amount of land abandoned.**—Mr. WHITNEY, Chief of the Bureau (formerly Division) of Soils in the United States Department of Agriculture, says large areas in the New England States have been abandoned; large areas in the Southern States have been practically abandoned and given over to waste, and large areas in the Far West which were once settled have been abandoned or are held in very low esteem. (859.)

Mr. Whitney says agriculture has been at a low stage in New England, particularly during the last 10 or 12 years. Many tracts have been abandoned and many people have moved away. These conditions are due to causes other than the poverty of the soil, and there is no reason why the agriculture of that country could not be built up and made more profitable than ever by adjusting it to new conditions. (867.)

Mr. BACHELDER says the abandonment of farms in New England began about 50 years ago, and continued until about 10 years ago. It was due primarily to the development of the West, which reduced the profit of New England farms and drew young men away, and also to migration to the cities for the sake of social enjoyment. Most of the farms abandoned are still owned by individuals, and the taxes paid; they have not reverted to the State, as some suppose. Ten years ago there were in New Hampshire about 1,000 farms having buildings suitable for occupancy which had been abandoned, out of a total of 32,000 farms in the State. Besides these a good many farms in more distant and mountainous places were so completely abandoned that no buildings remained, and these can probably no longer be made profitable for cultivation. (40, 41, 43.)

Mr. SPEAR testifies that there are not as many acres tilled in Vermont to-day as there were 40 years ago. A great many of the farms remote from town are now used as pastures. Some are being devoted principally to the growth of timber. (408.)

Mr. FLANDERS does not know of any abandoned farms in New York. (999.)

Mr. COLES, of Woodtown, N. J., says there are no abandoned farms in that section. (124.)

Mr. WEIDENBURN says some land has been sold to the State for taxes in Virginia, but he knows of no abandoned land. The farmers' houses are generally occupied. (622.)

2. Causes of abandonment.—Mr. WHITNEY names as the first cause of the abandonment of lands the development of new areas and new agricultural industries, and the competition of the more easily tilled lands of the West. The opening up of the grain-producing States of the West, particularly the wheat lands of California and of the Red River Valley, and the introduction of white burley tobacco in Ohio and Kentucky, have had a great influence upon the agriculture of the Eastern States. As the second cause he names the increase of factories and the demoralizing effect of factory life and factory wages upon farm people. With the feeling that the old conditions have changed, there is a lack of that business planning and management that would enable the farmers to fit their farming to new conditions. Among other causes contributing to the abandonment of lands, Mr. Whitney mentions unfortunate ventures in bringing people from a distance to settle regions with which they are unfamiliar; the selection of localities in which the climatic conditions are unfavorable; in the West, the scarcity of water in the arid regions, excess of minerals in the water or soils, and the deterioration of the ranges and consequent injury to the cattle industry; flooding by storms and tides; the difficulty of maintaining proper physical conditions in the soil, e. g., the trouble and expense of clearing the stones off the New England fields; cheap transportation and discrimination in freight rates against certain localities; and the difficulty of getting suitable farm labor for truck farming. (860-868.)

Mr. Whitney thinks that in the New England States, even more than in the South, the restless desire for material advancement and the higher education has been felt, because of the greater density of population and other conditions. Another contributing cause to the tendency in New England has been the demoralizing effect of the summer boarders upon agriculture. Moreover, the severe climate has been against the development of agriculture in some cases. The development of the West, and the lower price of farm products, brought about by the development of transportation systems, together with the increase in the number of factories and the restless desire of the people to enter the world of commerce and industry, have contributed in a marked degree to depreciation of land values in New England. (870.)

Mr. Whitney says that soils in Connecticut have been abandoned because of deficient rainfall, although there is a rainfall of 40 or 50 inches. The Windsor sand, which occasionally produces very fine tobacco, is so coarse and leachy that it dries out, and is subject to such disastrous droughts that the conditions are favorable only about 2 years out of 5. The expectation of getting a crop even 2 years out of 5 has induced many farmers to hold on until finally there have been successive seasons of failure, and they have had to give up. These coarse, sandy soils are found all the way along the Atlantic seaboard and the Gulf, and many farms have been abandoned on these areas. (862.)

As an instance of failure, due to unfavorable climatic conditions, Mr. Whitney mentions the conditions in Kansas and in portions of Nebraska and Colorado, settled during the boom times of 15 and 20 years ago. Cotton mills were put up in semiarid regions of Kansas and Nebraska, and are still standing as monuments to the unfortunate ventures that were tried. (861.)

Mr. BACHELDER says that chief among the causes of abandoned farms is the development of the West, and the opportunity it offered for young and energetic men. There has also been a desire for more social enjoyment than was available on the farms, and young people have gone to cities and villages for the reason. (40, 42, 43.)

OXLVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Professor BAILEY, of the Agricultural College in Cornell University, thinks that many farms that are now abandoned would never have been settled if the more fertile lands of the West had been accessible at the time. All the accessible and more fertile lands of the East are still good farming areas. While the abandonment of farms in parts of New York and New England may work hardship upon the present generation, it is a necessary economic change and will in the end produce good results. (1012.)

Mr. AGER attributes the large amount of abandoned land in Maryland to the following causes: During the period of slavery the land was owned in large tracts, and when the slaves were freed the planters, thinking that they could not do anything with hired labor, gave up the attempt to farm their lands and mortgaged it to get means of support. In this way the land fell into the hands of merchants in Washington, one grocer owning perhaps half of Prince George County from having to foreclose mortgages. Another cause is the exhaustion of the land by continual cropping. The abandoned lands in Prince George County sell from \$6 to \$10 an acre. They are being taken hold of and reclaimed more than formerly. All they need is intelligent cultivation. Dr. Ager once remarked to a gentleman near Marlboro that the land should be sown to clover, but he replied that the farmers did not want to raise clover when they could get fertilizer in Baltimore by signing a note. (109.)

Dr. CROWELL says that when agriculture reaches the point where the returns on capital and labor are declining, land will be thrown out of cultivation unless new methods or new agencies are introduced. In the East, where the productivity of the soil has declined to the point where it ceases to compete with the richer soils of the West, it has frequently passed out of cultivation until a new kind of agriculture, such as market gardening, has been introduced. That has taken place in Massachusetts, New Jersey, Pennsylvania, and along the Eastern coast. The decline in productiveness is no proof that the land is not going to be a profitable field of investment in some direction. (344.)

3. Purchase of abandoned farms in New England.—Mr. WHITNEY thinks there is already a reaction going on against the abandonment of farms in New England. A considerable portion of the land has been taken up in recent years by French Canadians, and many abandoned farms have been annexed to neighboring farms, so that their cultivation has generally been continued. (866, 867.)

Mr. BATCHELDER says the State of New Hampshire began the movement, which was followed by other New England States, of advertising these abandoned farms for sale and otherwise seeking to bring them back into use. Three-fourths of those in New Hampshire have been taken up, and the movement in the other States is in the same direction. Most of the persons who have taken up the farms are Americans, many of them farmers and residents of New England who had gone West, and in some cases people returning from the cities. A considerable proportion of the farms have been taken by people of wealth for summer residences. Considerable investments have been made in improving farms of this class, so that in some cases the assessed valuation of towns has been increased. The prices of land have varied greatly according to the distance from the railroad, the fertility, and in many cases the scenery. (41, 42.)

Mr. STOCKWELL says there are partially abandoned farms in Massachusetts, but the State has been doing something, with success, toward repopulating them. They are being sought for, and the outlook is brighter. The last time a new edition of the catalogue of abandoned farms was prepared, the number of returns was very small in comparison with the earlier editions, demonstrating that agriculture is improving in Massachusetts.

Mr. Stockwell says the abandoned farms are being taken up, not by recent immigrants, but the immigrants of years ago who have become citizens. Of 269 purchasers, 159 were residents of Massachusetts, 14 of New York, 10 of Connecticut, 5 of New Hampshire, and the rest scattering or unknown. So far as he can judge 151 were Americans, 14 Irish, 8 Germans, 7 French, 4 Scotch, and the rest unknown. Massachusetts was largely her own purchaser. During about 2 months in 1899 73 requests for catalogues were received by mail, besides many individual calls at the office. Twenty-nine of these requests were from Massachusetts, 17 from New York, 5 each from Connecticut and Pennsylvania, 3 each from New Jersey and Vermont, 2 from Nova Scotia, and 1 each from New Hampshire, Canada, North Carolina, Michigan, Ohio, Texas, Illinois, and Tennessee. Those who have gone in past years from Massachusetts to the Far West frequently write as to the conditions, and desiring to return. (893.)

Mr. Stockwell says that a few years ago land was so cheap in Massachusetts and the adjoining States that people, seeing that that condition could not continue, bought it for investment. There is now more desire to retain the farms in Massachusetts, and there are practically no abandoned farms. (901.)

B. Migration to cities.—1. Prevalence of the movement.—Dr. CROWELL thinks the general tendency of intelligent farmers' boys has been toward the professions and business in the city. Many are drivers of trucks, or street-car drivers and conductors. The Navy has enlisted a considerable number. As a rule the farmer's boy gets a greater number of days' employment and a greater profit in the city than in the country if he finds employment. As a rule he makes a much more efficient employee than the city-bred boy, and is naturally selected for his fidelity and perseverance. Dr. Crowell thinks there is nothing alarming in this migration to the cities if people are free to go and free to return, and if the dollar of capital put into the farm holds out as good a prospect of profit as a dollar put into city enterprises. In France farmers' boys go to the city and work to accumulate capital, and then go back and buy land to fall back upon when work is slack, or as they grow older. In this country that process has not yet begun to develop, but is likely to grow out of the development of transportation facilities from city to country. (338.)

Mr. POWERS says that in the exodus from the farm to the town there is a larger proportion of farm owners than of farm laborers. They have a little money and are in better shape to avail themselves of the opportunities of the city. They go to the cities and make the backbone of the Republic. Many of the leading men of the cities were originally farmers. The movement to the city is no new thing; it has been going on for centuries, and will continue. (178, 179.)

Mr. HALL does not think the tendency to go to villages and towns is any greater among the whites than among the blacks in the South. (401.)

Massachusetts.—Mr. STOCKWELL, secretary of the Massachusetts State Board of Agriculture, says that 40 years ago the hill towns were engaged in various manufacturing enterprises, and the land was regularly laid out in fine farms. Business of all kinds was prosperous. The farmer was making money and bringing up children whose influence is now felt throughout the Union. The decline of the manufacturing industries in the hill towns is greater than the decline of agricultural industries. The proportion of abandoned wagon shops, shoe shops, sawmills, etc., which were once the life of flourishing villages, has outstripped the abandonment of the farms, and much of the so-called decadence of the hill towns is due to the changed methods of manufacturing industries, which have concentrated the work in large plants with improved machinery, thus drawing the workmen to the large towns. (888.)

New Jersey.—Mr. COLES, of New Jersey, says a great many of the children of farmers leave the farms, but the farms in his section are all occupied. If the farmer has two or three sons, he can not find room for them all unless he cuts up his farm or buys a neighbor's. It is only now and then that one who leaves the farm for another occupation succeeds better than the one left on the farm. (125.)

Mr. KETCHUM, of Pennington, N. J., says the tendency with the brightest and best young men in that section is to leave the farms and go to Trenton or other cities to enter the professions or mechanical pursuits. Agriculture is considered too slow and too laborious a way of making money, and the difficulty experienced in getting reliable farm help has led a good many to give up agriculture. (133, 138.)

Pennsylvania.—Mr. HAMILTON testifies that at the end of last century nearly 89 per cent of the people of Pennsylvania lived outside of incorporated towns and cities, and almost the entire number were engaged in agriculture in some form. In 1890 only 44 per cent lived outside of incorporated towns and villages, and only about 21 per cent are now engaged in agriculture. (365.)

Minnesota.—Mr. MORAN, of Graceville, Minn., testifies that the tendency of young men to leave the farm is increasing. (709.)

West Virginia.—Mr. CLOHAN, of Martinsburg, W. Va., says farm labor seems to be less efficient than formerly, because the most intelligent young men leave the farm and go to the city, where the hours of labor are not much more than one-half as long and the wages fully one-half better. (591, 592.)

Kentucky.—Mr. NALL testifies that there is a tendency among the agricultural laborers of Kentucky to seek other employment. Being largely colored, they like to get together and live in groups in the suburbs of a town. Many are also drifting to large cities, where the factories employ them at better wages than they get on the farm, though the cost of living is also greater. The handling of tobacco is an important line of work in the factories employing many of these hands, and they seem to be fond of that kind of work. Every factory employs some teamsters, etc., at least. A colored teamster makes pretty good wages. (804.)

South Carolina.—Mr. HAMMOND, of South Carolina, says that the census showed 29 per cent of the population of his State engaged in agriculture in 1870, 30 per cent in 1880, and only 20 per cent in 1890. His observation confirms the conclusion that the agricultural population is proportionately decreasing. His own township, a purely agricultural community, decreased in population by several hundred between 1880 and 1890. Five families left in the year 1900. (816.)

Georgia.—Mr. PECK, of Georgia, says prices have not been remunerative, and there

is a disposition on the part of both white and colored and both laborers and landowners to get away from the farm to other employment. In some sections of Georgia the farms are turned over entirely to the tenants, the landowners having left. The majority of men in Georgia would go into other business if they could get out the capital they have invested in farms. (459, 460.)

Mr. STEVENS testifies that within the last 50 years the population of Georgia has increased 144 per cent; the 5 largest cities in the State have increased in the same time 427 per cent, and the urban population of the State as a whole at an even greater rate.

Alabama.—Mr. POOLE, Commissioner of Agriculture of Alabama, says there is a great disposition among the young white men of the South to leave the farms and go to the towns. The same disposition exists somewhat among the colored people, because they are rather imitative. There is a disposition among the younger negroes of the Black Belt to go to the mining districts for higher wages, but after working there a few months they generally drift back to the plantations. (919, 922.)

Mr. DILLINGHAM, of Alabama, says the negro boys and girls are beginning to drift to the cities to help fill the slums. (167.)

Tennessee.—Mr. GODWIN, of Tennessee, says the best labor is in the cities. Young, strong men go to Memphis, where they can get better pay than farmers can afford to give. The planters get the old men, women, and children. (476.)

Louisiana.—Dr. STUBBS testifies that agricultural laborers are being lost to Louisiana in considerable numbers, particularly along the railroads and rivers. They go to villages and cities or to work on the railroads and levees. Dr. Stubbs has found 2,500 colored men working on the levees at Cairo, Ill., a great number of whom were from Louisiana. (770.)

Cotton-mill laborers in the South.—Mr. HAMMOND says that the white people who are now in the Southern cotton mills were not before doing work in competition with the negro. He thinks they were largely managers of little farms. (833.)

2. Causes of the movement.—Professor DAVENPORT enumerates the following fundamental reasons for the migration of farm laborers to cities: (1) A large proportion of humanity is strongly desirous of an exciting environment; (2) farm labor is more exacting in the range of ability it requires than most of the labor in the city, which is so organized that the labor of any one individual is comparatively simple; a man on a farm is expected to do a great variety of things, and is left a good deal to his own resources; (3) the wages paid in the city are apparently higher; there is a strong tendency to compare money wages in the country with money wages in the city, and to disregard the value of board; (4) the country has experienced a wonderful development along mechanical lines, and the American is naturally a mechanic, while until very lately farming has hardly been considered a scientific or skilled occupation; (5) a great many young men feel that farming is degrading. (257, 258.)

Mr. HAMILTON mentions the following causes for the growth of cities and the diminution in the percentage of agriculturists: (1) The hope of gain and opportunities for advancement the cities present to young men; (2) the absence of suitable rural schools; (3) the difficulty of access to the country because of poor roads. (365.)

Mr. STOCKWELL explains the migration of agricultural laborers to cities substantially as follows: (1) Farm life is secluded, and there is a great desire to huddle in the larger centers; (2) the feeding of stock and other chores makes the day longer on the farm than in a mill; (3) agriculture is a strenuous life, strong, healthy labor, not sitting on a stool and guiding machinery. "Too many prefer the stool, or, if life must be strenuous, wild cats and wild oats are more attractive." Mr. Stockwell fears that hard labor is not as attractive as formerly. (885.)

Mr. Stockwell dates the beginning of the decline of New England agriculture from the concentration of industries in large centers. Twenty or forty years ago Massachusetts was alive with little industries, and on every water power was a mill or some little manufactory. The shoe business was done in the various towns, the young people from the farm houses doing the work. This all brought a certain amount of life, and the home market brought a certain amount of money to the town, and everything was prosperous until the industry moved away to a larger center. It took with it the young laborers, and the support given to the church and the school; in consequence, the farmer had the whole burden to bear, adding very greatly to his taxes, and the discouraging fact of his sons and daughters going away led to his going after them and the farm being abandoned. (889.)

Mr. J. C. HANLEY, national organizer of the National Farmers' Alliance and Industrial Union, gives the following reasons for the inclination of young people to leave the farm and seek employment in the already overcrowded cities: (1) The ambition to achieve greatness and prosperity, which is deemed impossible on the farm; (2) the monotony and irksomeness of farm life and the yearning for the amusements and

excitements of the city; (3) the drudgery and small pay on the farm in contrast with the better wages and shorter hours in the city; (4) the lack of home comforts and pleasant surroundings. (275, 276, 285, 286.)

Mr. POWERS says that a given number of men can produce as much food as twice the number could 50 years ago; something must be done to give the extra men employment, and they find employment in manufacturing, transportation, and other industries. The increased productivity of labor on the farms makes it possible to sustain the life of great numbers, and the progress of these others in turn helps the farmer. With some people the poorer facilities for education and inferior mail facilities in the country have something to do with the tendency to go to the cities. (174.)

Mr. BRIGHAM calls attention to a considerable migration to the city, not from necessity, but because men enjoy employment in the city and the company which they secure. There is a marked tendency for the boys brought up on the farm to seek other occupations. They often desire to be doctors, lawyers, or merchants. This tendency is partly due to a failure to appreciate the comforts of farm life, especially the advantage of supplying a large proportion of the necessities of life directly, without purchase. It is the aim of farmers' organizations to make farm life more attractive and profitable so as to keep young men on the farm. (7, 8.)

Mr. WHITNEY says the social conditions of New England have changed in the past few years. The growth of the factory system, the increase in wages, the increase in the variety of articles considered necessary for comfort and health, the general increase in the cost of living, the general feeling of discontent, and the unwillingness to remain in the laborious life of the farm have all had their influence. Of all of the causes that have contributed to the abandonment of lands in New England, no factor has been more potent than the success of individuals in commercial and industrial lines and the apparent ease and luxury of their lives as compared with the laborious and simple life of even the successful farmer. (866.)

Mr. Whitney adds that there is a general feeling among the farmer boys in New England that they want the higher education and want to take up the professions. Young men have a great ambition to get into electrical work on account of the high wages, and there is a desire to go into commercial and industrial lines rather than to remain on the farm, except in the communities in which special crops and special agricultural interests are being developed. (868.)

Professor DAVENPORT says the rapid development of the country seems to require the frequent meeting of men interested in large enterprises, and thus tends to form centers of population favorable to the rapid conduct of business. (258.)

Mr. KETCHUM, of New Jersey, says the tendency of the best farm labor, such as was available 30 or 40 years ago, especially in the case of Americans, has been to leave the farms and go to the city, partly because they could get higher wages, and partly because the members of their families could get work at fair wages. These causes, together with social advantages of the cities, have drawn the best American labor away for a radius of 30 or 40 miles about the city, and after they are in the city with their families they can not be induced to return. (137.)

Mr. DYE attributes the movement partly to the depression of agriculture, partly to the hope, often unrealized, of securing high wages and short hours in the city. Young men hope to get rich quickly by going to the city, but statistics show that a large proportion of them fail to make money by doing so. The desire for the social advantages and amusements of the city is also a strong influence. Young men and women also tend to consider farm labor unpleasant and dirty, and want to go into something more stylish. (84, 91, 92.)

Mr. GREELEY, of South Dakota, says many people rent farms that are not good land, or think they are farmers because they have bought a piece of land, and make failures of farming and become discouraged. There is also the idea that the farmer must be a drudge—must get up earlier and work later than other people. Many boys and girls are worked so hard on farms that the thought of farming is distasteful forever afterwards; but this is all wrong, and the advanced agriculture of to-day warrants as much leisure and as pleasant homes as any other profession. The farmers are adopting better machinery and more reasonable hours. Not long ago, to be considered a good farmer one had to be up with the whole family at 4 a. m., and to keep them on the jump until 10 p. m. was considered especially commendable; but to-day the reverse of this is becoming true in the best farming sections. The man who, after his land is paid for, finds it necessary to get his family out of bed at 3 or 4 in the morning in order to make a living is not an up-to-date farmer. He generally lacks in management or intelligence, or is miserly. (935, 936.)

Mr. WHITE, of North Carolina, thinks perhaps the leading reason for the migration of negroes to the cities in North Carolina is the oppressiveness of the landlord and

tenant act, which reduces them to serfdom. There is nothing for them to look forward to on the farm, and they lose hope and go to the cities. (428.)

Mr. REDDING thinks the disposition of a young man brought up on a farm is to go to the city, where wages are better than in the country. Agricultural labor is not well paid, and even those farmers who are making money and paying fair wages can not always keep their sons on the farm. Under the old régime the sons worked on the farm, and when 21 or 22 years old married a farmer's daughter and were given part of the land, or were helped to buy a farm close by, and given a couple of mules and a few negroes. It was an easy matter for a farmer's son to get a farm. Farmers can not now set their sons up as they used to, and young men do not like the idea of starting out with nothing, so if they have a little education they will go to town and hire out at almost anything. They are paid off every Saturday night or twice a month, while the farmer has to wait until his crop is matured, and unless he has credit has a very hard time in the meantime. There are scarcely any social opportunities in the country; the roads are bad; post-offices and churches are at a distance; there are no electric lights and street railroads, shows, and pretty things to see. These, Mr. Redding says, are what attract young men to town more than anything else, and after they see the railroads and electric lights, and enjoy the social functions, etc., they dread work, common clothes, and lack of style. (449, 451.)

Mr. GEORGE attributes the migration of young men away from the farms to the monotony and drudgery of the farm as compared with the attractions of city life. Mr. George says that until the farmer's son is educated in his pursuit, as other classes are for their callings, he can not have a real interest in the farm; ignorant labor is drudgery. The agricultural colleges do not receive more than one in a hundred of their students for the purpose of educating them in the conduct of farms. (224.)

Mr. WILSON testifies that the native-born citizens of Illinois, a great many of whom were formerly agricultural laborers, have largely gone into the towns, where the financial and social conditions were considered better. He thinks there is not as much feeling that other vocations are more respectable than agriculture as there was 20 years ago. The young farmer of to-day believes he is as good as any other man, but perhaps thinks that other vocations offer a better chance to rise. Mr. Wilson mentions the presence of foreigners as one cause of the migration of the native born to cities. (243, 246.)

Dr. CROWELL says that in many sections of the country the process of exhaustion of rural capital has gone on until men could not borrow any capital to keep up their farms, and had either to take up new lands where little capital and labor were required, or to go to the city and work for wages. This process is not found in the colonies of foreigners. (334.)

Dr. Crowell adds that the economic traditions of the New England farmer are entirely different from those of the European farmer. In the former there is much more of the speculative, more of a disposition to meet demand through the distributive system rather than to wait for the productive processes of nature. He is a man of the city rather than of the country. (335.)

Referring particularly to the South, Dr. Crowell says the rewards of manufacture and of working for wages in factory villages are so great comparatively that as few people remain on the land as possible. (335.)

Mr. NUNNALLY attributes the tendency of young white men in the South to leave the farm to the low prices of products. (457.)

Mr. GRAHAM testifies that the cotton mills have drawn heavily upon agricultural labor in the South, and that a man will buy a piece of land, rent it to another man, and come to the cotton factory to make the money to pay for it; not because factory labor is preferred, but he gets cash pay every Saturday night. The poor returns from farming and the large families help to induce the movement to factories. Mr. Graham says the movement to the factories has a bad effect in some instances, as where a man puts his family into the factory and spends his time loafing, but that is the exception. (435.)

Mr. NORRIS says Americans have an idea that speculation is more congenial to them than work on a farm; so they go into speculation and leave foreigners to do the work, "and the first thing they know they have speculated out and the German owns the farm," and the original owners move to town. The American has a family of children who think they are too nice to work with their hands, and must teach school or work in a store, or something of that kind. (323.)

Mr. M. F. GREELEY says so much improved machinery has been introduced in Minnesota and the Dakotas that there is very little steady employment, and farm laborers can not rely on employment the year round, so those who like to have steady employment go into other occupations. (928.)

Mr. NALL testifies that there is a tendency among the land owners of Kentucky to leave the land in the hands of tenants and drift to the cities, where most of them

buy houses. Mr. Nall attributes this tendency to the advantages of the schools and churches, and to the lack of household help in the country. A good many Kentucky farmers have moved into Louisville and other cities and towns to get the benefit of high schools for their children. (814.)

Mr. STEVENS attributes the tendency of the agricultural class of Georgia to drift into the cities largely to the better educational advantages in the towns, but says the young white man goes to the city because he believes he can make a larger fortune in a shorter time there than by farming, while the negro drifts into town by the promise of a little higher daily wages, forgetful of the fact that the increase in cash does not nearly make up the items furnished him free of cost on the farm. The result is that many become loafers, beggars, and criminals. (908, 915.)

Mr. MORAN, president of the National Grain Growers' Cooperative Association, says there is nothing in our school text-books that will show the farmer's boy the nobility of his calling and the greatness of the enterprise his father has engaged in; so instead of being proud of his occupation he seeks to throw off the yoke and go to the city to get away from the drudgery of the farm and enjoy city life. The hours of labor on the farm are long, from early dawn until dark, and often into the late hours of the night, and the remuneration very small. The boy on the farm is deprived of good clothing and of reasonable time for leisure or pleasure, and is deprived of schooling to work on the farm during the busy times of seeding and harvest. (709.)

3. Remedies.—Mr. HAMILTON believes that the introduction of a better quality of rural schools and of good roads would keep in the country many who would otherwise leave, and bring into the country from the towns and villages large numbers of the better class of people, who would prefer the country if it were made accessible and the comforts and conveniences could be had in the country. Such conveniences as good roads, inexpensive lighting apparatus, and the placing of water and heating apparatus in houses are taking many thousands of people out into the country. (365.)

Mr. STEVENS's remedy for the drift to the cities is better rural churches and schools, more attractive homes and tenant houses, improved roads, and better mail facilities. (906.)

The remedy Mr. NALL suggests for the migration of the colored laborers to the cities is to make them happier in the country; to recognize their social interests; to make their homes more comfortable, and regulate their morals; to establish schools and churches, and improve their condition and ambition, if possible, so as to encourage the better class to stay in the neighborhood of large farms. (804.)

Mr. HANLEY, being asked to suggest a remedy for the migration to the cities, expresses the belief that if farming can be made profitable the social conditions of the farmer will be reversed. He will have the necessities and some of the comforts of life, perhaps have his children educated in some of the accomplishments, and have books and papers in the house. (275.)

Mr. M. F. GREELEY, of South Dakota, thinks the only way to cure most of those who get "city struck" is to have them live in the city at a fair salary and find themselves in debt every Saturday night and at the end of the year. A few years of this generally sends them back to the farm in a frame of mind to appreciate it; but too frequently there is no farm to go back to. (934.)

Mr. POWERS says that to send a man who knows nothing of farming into the country as a farmer is to inflict a great injury upon the community and upon the man. The only way to take such people out to the farms is by giving them a schooling of 3 or 4 years. Whenever there is an overpopulation of the city and a deficiency in the country, however, a certain number of people can be utilized as farm laborers. (184.)

Mr. Powers thinks that so far as the tendency to seek other employment needs a remedy, it will be found in a wider education of farmers in the science and practice of agriculture. A wider knowledge of the factors of business success is needed on the farm. As the farmers are educated and acquire intelligence, foresight, and energy, and see that the farm gives opportunity for the exercise of these virtues, any undue movement to the cities will be checked. (172.)

4. Reaction from the movement.—Mr. SPEAR testifies that the great drift of people from the farm and from the State that has characterized the Eastern States in the past has largely passed away during the past decade. He thinks the opportunities in other lines of industry than agriculture are not as great as they were 30 or 40 years ago. (402.)

Mr. NORRIS, master of the New York State Grange, says that for a period of years beginning in 1890 there was a tendency for the brightest and best men in the rural districts of New York to go into railroading or move into the cities, on account of the demand for laborers and the attractive wages paid at that time; but since 1896 or 1897 there has been a tendency to return to the farms.

Mr. Norris has noticed that a great many people who have been living in towns

and cities, having abandoned farming and gone into something else a few years ago, have been returning to the country, renting farms or working them on shares. (320-322.)

Professor DAVENPORT says (1899) that there have been many indications in the last 3 or 4 years that the tendency of farmers' sons to leave the farm has received a check. He thinks there is a stronger tendency on the part of farmers' sons to remain on the land than 5 or 10 years ago. He knows a great many farmers' sons who have trained themselves for electrical engineering and other technical professions, and then quickly abandoned these professions and gone back to the land. (256, 257.)

Mr. WILSON testifies that the tide is turning from the city to the country. Workmen are going from the cities to the country in Illinois to work as farm laborers. Two such men came into Mr. Wilson's neighborhood in 1899. (245.)

Mr. BUDGE, of Grand Forks, N. Dak., says there is no disposition on the part of the farmers to leave the farms, and some people from the towns take up farming. He thinks more people are moving onto farms in his section than are moving away from them. (852.)

Mr. FROM, of Milton, N. Dak., testifies that in that neighborhood the young men do not seek other employment than agriculture, but remain on the farms, as a rule. (788.)

Mr. M. F. GREELEY, of South Dakota, says the disposition on the part of the farmers of that section to leave the farms for the cities is very rapidly growing less. (935.)

Mr. STREVENs thinks the tendency on the part of the agricultural class of Georgia to drift into the cities is possibly not as great as in the past. (915.)

C. Interstate migration.—1. The westward movement in the South.—Mr. GRAHAM, of North Carolina, says that when the Cherokee Indian lands—and afterwards Mississippi and Louisiana—were opened, a great many people in western North Carolina sold their land and went to those places, leaving a large number of abandoned fields. This emigration having ceased, the country has filled up with laborers, so that there is a much larger number engaged in agriculture than formerly. (435.)

Mr. NALL, Commissioner of Agriculture of Kentucky, testifies that for 10 or 15 years there has been a considerable tendency for Kentucky farmers to move West to cheaper lands in other States. (811.)

Mr. HALE, of Fort Valley, Ga., says there is very little migration from that section to other parts of the country, but a few farmers go to Texas and Arkansas, where they think the land is more fertile. (388.)

2. Migration from North to South.—Mr. AGER says that a great many of the farmers in Maryland are native Marylanders, but quite a number of Northern and Western men have come in during the past 20 years. (109.)

Mr. GAGE testifies that there has been a great deal of immigration from Northern States into the the Delta country. At first the Northern farmers operated their places as they did the grain farms of the Northwest, but they gradually worked into the customs of the men they employed. Those who have worked hard and lived economically have usually made a living. (493.)

Mr. BALCH testifies that in 1898 and 1899 there was considerable immigration from Nebraska to two or three counties of Arkansas. The farmers from the North are engaged in general agriculture. They turn a little more to grain and stock raising than the Southern farmer. (496.)

3. Migration to the Northwest and to Canada.—Mr. SMITH, director of the Michigan Experiment Station, testifies that the depression of agriculture in Michigan, following upon successive failures of the wheat and other crops, has become so great that agents of the Canadian Government and of railroad companies owning lands in the Dakotas and surrounding States have succeeded in securing a large migration of agriculturists westward. During the first few months of 1900 several hundred people, chiefly tenants and laborers, migrated from Shiawassee County alone; a train load went at one time and a considerable number of laboring men at another time. This migration renders the problem of securing sufficient help very serious. The Canadian Government maintains a general agent, in charge of special agents throughout the State, who are securing the migration of citizens to the Canadian Northwest. (566, 567.)

Mr. JUMPER testifies that 5 or 6 years ago many farmers migrated to Winnipeg and to northwestern Canada from South Dakota, but he thinks nearly all of them came back, and are now quite satisfied to remain. (734.)

Mr. BRIGHAM says that, compared with former times, there is now very little migration of farm laborers from Ohio to States farther west and northwest. (7.)

Mr. BUDGE says there are some settlers in North Dakota from the older States, nearly all farmers and good citizens. Some of them who were better off than the others when they came had some stock in cattle. Some Dunkards from Pennsylvania moved into settlements by themselves, and are doing very well. (847.)

D. Public lands.—1. *Working of the land laws in the past.* (See also *Foreign and Western competition*, I C 1, p. LXXXIV, and *Reasons for the decline in value of Eastern lands*, I E 5, p. LXXXIX.)—Dr. CROWELL explains the extraordinary development of American agriculture as due mainly to free land and the admission of foreign labor to occupy it. (338.)

Mr. PROM says the settlers of North Dakota generally acquire their titles under the homestead law, and in early days by the preemption and timber claims. Many men got three claims adjoining, making very valuable farms. The land was mainly sold by those who first took it up, or they piled up mortgages and took the money, and the lands went to the loan companies, who have now resold, however. (789.)

2. *Remaining National and State lands.*—Mr. MEAD submits a table showing that the 15 arid and semiarid States, having a total area of 959,213,440 acres, contain about 48,912,353 acres in Indian reservations, and 528,958,630 acres of the national domain still undisposed of and unreserved. (1063.)

Mr. POWERS says there is a larger amount of land available for cultivation and settlement than the pessimists can imagine, but less than some of the most hopeful people think. There is quite a large amount of railroad land, and some State lands, that have never been settled. In Minnesota there are large bodies of pine lands which will ultimately make good farms. (182.)

Alabama.—Mr. POOLE says there are in Alabama public lands open to settlement, and some State lands open under homestead laws. There are no very desirable lands left, but there are some swamp and overflow lands. Nothing has been done to reclaim the swamp and waste lands of Alabama. They remain subject to entry on payment of a small fee. (922, 924.)

Mississippi.—Mr. KYLE testifies that Congress originally donated a township of public land in Mississippi for seminary purposes, the proceeds of which were put to the credit of the University of Mississippi. More recently, while a member of Congress, Mr. Kyle got a bill through donating another township of public land, on the theory that the new States had received 2 townships. The State of Mississippi owns a good deal of land, chiefly forest, but not nearly as much as formerly. The practice is to sell it. (469.)

California.—Mr. NAFTZGER says that the larger part of the mountainous and hilly land of California is owned by the United States Government, and 2 sections in a township are school land. The Southern Pacific Railroad Company owns large bodies of land in the deserts and mountains, included in the grant made to promote the building of the road. Some regions are covered by Mexican grants, and there are some other very large estates. The Mexican grants are usually held by San Francisco people, seldom by residents upon the lands. They are largely owned by people who have acquired them by foreclosure, or by even cheaper methods. The original holders, being Mexicans, were improvident and squandered them in riotous living. Where there is water to irrigate these grants they are being cut up and put into diversified farming, fruit raising, etc. Very large areas of them, however, are grazing lands, originally granted about a pool, a spring, or a stream of water. (951, 952.)

State lands under lease.—Mr. MEAD submits a table showing that in 6 Western States the acreage of State lands under lease at the close of the last fiscal period ranged from 32,272 acres in Idaho to 1,969,945 acres in Wyoming, while the average rentals per acre ranged from 4.1 cents in Wyoming to 61.4 cents in Idaho. (1064.)

3. *Need of protection to grazing lands.*—It seems to Mr. WHITNEY that it will be necessary to adopt some legislation to protect the ranges of the West and prevent the destruction of property caused by close grazing where there is no restriction. Where range lands are rented for 5 cents an acre little expense can be devoted to their improvement; and where land is so cheaply rented or purchased and so carelessly used there is little chance to make any improvement in agricultural conditions. Much of the damage occurs on the public domain. (861.)

Mr. MEAD estimates that more than 400,000,000 acres of the public lands are valuable for pasturage alone, and predicts that it will be necessary for the Government to exercise some control over these lands in order to prevent controversy and preserve the grasses from destruction by overstocking. If a leasing system could be devised which would so unite the grazing and irrigable lands that each irrigator would have a right to lease a small area of the contiguous pasture land a larger income would be received from rentals and both the agricultural and grazing interests put on a more secure footing. (1063.)

Mr. Mead says the objection to the disposal of public land by absolute title is that some of the land so disposed of for grazing purposes may be irrigable. He thinks the better plan for the present as a tentative measure would be a lease system. He would limit the term to 5 years, and would have every tract of land leased remain subject to entry under the public land laws; otherwise it would be necessary to have an economic survey to distinguish between the irrigable and the pasture lands. There are between 300,000,000 and 400,000,000 acres of public grazing lands. (1066.)

1. Relative advantages of city and country.—**1. General advantages of country life.**—Mr. GEORGE thinks farmers make a mistake in allowing their sons to go to the village to stand around the street corners in search of opportunities. If they would organize they might have a much better social environment, and advance the intelligence of those in search of opportunities in agricultural districts. (222.)

Mr. MASON and Mr. EDMONDSON, prosperous colored farmers, think the opportunities for a young colored man better in the country than in the city. (500, 502.)

Mr. GODWIN thinks his tenants are in a condition to keep their families as comfortable as if they were laborers on city streets. (479.)

Mr. GREELEY says that if the farm laborer has children it is much better for them to live in the country. They are more than twice as apt to make strong, self-supporting citizens than if they grew up in idleness in crowded cities. (928.)

In Mr. MORAN's opinion young men do not better their condition by leaving the farm for the city, but make matters worse. "They seem to forget their training when they come to the cities," and fail to make themselves homes, as they would if they remained on the farm, for when the farmer dies his land is divided up among his family. The farmers raise their own things on the farm, except the clothes they wear, and do not look upon their living as costing anything. (709, 710.)

Mr. HANLEY says the lonesomeness, monotony, and mental anxiety endured by farmers' wives and daughters causes them to break down and contribute a large percentage to the inmates of insane asylums. On the other hand, the discontented young men and women, coming abruptly in contact with city associations and freed from the restraint of parental watchfulness, often become victims of low social conditions and vice.

Mr. Hanley thinks that the inferior social conditions of farm life are the result of unprofitable farming, and will not be improved as long as farming remains unprofitable. (286.)

Professor BAILEY, of Cornell University, declares that half the value of farm life is in the satisfaction of living it. If the farmer looks longingly toward the city, the city man often looks with equal longing toward the farm. The isolation of the farmer is disappearing under the influence of trolley roads, better wagon roads, neighborhood telephones, rural mail delivery, and books. The unattractiveness of the farm home is largely caused by the lack of opportunities for physical comfort, and much of this lack is remediable. The hard lot of the woman on the farm is also a serious cause of dissatisfaction. Her lot may be expected to improve, not merely with the economic status of the farmer, but with the introduction of a higher type of living quite independent of income. The condition of women on the farm is a fairly good index of the intellectual and social status of the community. (1013, 1014.)

2. Standard of living among farmers.—Mr. HOLMES maintains that in discussing the income of the farmer, the standard of living should be considered. The farmer is now, more than ever before, a citizen of the world; he has books and periodicals; he travels more than ever before; his children receive a better education than he received and dress better than he did at their age, and they are more frequently in contact with town life than he was; they have a top buggy instead of an old wagon. The farmer's food is more varied; more of it is bought and less raised on the farm than formerly. (157.)

Mr. POWERS says that it is unfair to compare the style of living of the uneducated farmer with that of the educated mechanic, but comparing it with that of the uneducated day laborer in the city, he thinks their living is about the same. The farmers are not as well off as city people who represent a higher type of life, but are comparable to mechanics and laborers with the same education, training, and thought. In the older sections of Minnesota there are as many pianos among the farmers as among the same grade of mechanics. In the newer section there are not so many pianos and organs, fine dresses, and fine wagons. Mr. Powers knows some farmers who live better than the average lawyer does. (174.)

Mr. GREELEY, of South Dakota, says the advanced agriculture of to-day warrants as much leisure and as tidy, up-to-date homes as any other profession. Rural mail delivery, telephones, and better roads and teachings all have much to do with this. (936.)

Mr. VAIL testifies that local telephones have been introduced in some sections of Vermont. He knows of one neighborhood which has a system of 10 or 12 miles of farm telephones, which cost the owners only about \$20 apiece to install, and he knows of no one thing that has done so much to put the farmers of that neighborhood in touch with the whole community as the introduction of that telephone. The women use it for visiting and arranging sociables and church matters, and in case of sickness a physician is called at a moment's notice. The telephone takes the place of the village. It requires but little repairing; some young man in the community will take

an interest in it, and some persons are as expert in the little things that need attention. There may be a few cents for repairs; but that is usually covered by the small rate charged for the delivery of messages from other telephone and telegraph lines. Mr. Vail has heard of wire fences being utilized for neighborhood telephones elsewhere, but that has not been done in Vermont. (415.)

Mr. Wilson says organized farmers have largely instituted the farm telephone, which he predicts is to be one of the greatest factors of civilization, bringing the farmer into closer relations with the world and keeping him in touch with the markets. Farm telephones are much in use in different sections of Illinois. By means of through reciprocal service with four systems Mr. Wilson, from his home in Magnolia, can talk to over 200 families. (250.)

Mr. STOCKWELL alludes to the wonderful development of electrical power during the past 20 years, and hints at the future possibilities of condensed and liquid air. (905.)

3. *Relative chances of economic success.*—Professor BAILEY believes that the proportion of successful men in farming is as great as in other callings, and probably even greater. (1014.)

Mr. HALE believes that with the same mental equipment there is a better chance to succeed in agriculture than in manufacturing or banking. If the young men in Yale, Harvard, and other high-class colleges would put the same energy and study into scientific agricultural education and apply it as farmers, their chances of making money and getting ahead would be greater than in the professions. (386, 397.)

Mr. KETCHUM knows of no occupation in which the average young man can be more certain of making a living than by buying a farm, if he can pay one-third or one-half down and is willing to work. If he will give close attention to farming he will perhaps succeed better than by putting his money into mechanical pursuits, if he is adapted for farming; if he is not, he might succeed better in another occupation. Mr. Ketchum thinks the inducements are as great for the ordinary farmer's son to remain on the farm as to go into the city. (136, 137.)

Professor DAVENPORT admits that the man able to control large interests is likely to come into that control more readily in the city than in the country, but says that farm laborers who would remain laborers, even of good grade, in the city, have a better opportunity of becoming men of influence in the country than in the city. (257.)

Mr. REDDING says the young man who goes to town will enjoy life, but unless he is well equipped he would probably do better in the end in agriculture. (451.)

Professor DAVENPORT says the land is kind to its occupants; one can go on a small piece of land and maintain existence with less effort than in any other calling. (259.)

Mr. CLOHAN, of West Virginia, thinks that in spite of the difference in the cost of living, an industrious and frugal young man can succeed better in the city than in the country. (591.)

Mr. GAGE, of Memphis, says a great many negro laborers leave the farms and go to Memphis. Thousands of them are on the street idle. Those who are employed on the streets by the street-car companies, Mr. Gage thinks, are paid \$1.50 a day; in building sewers, about \$1.25. Loading and unloading steamers on the levee by the hour is a large source of employment for negroes. Meat, flour, etc., cost less in the city if bought for cash than in the country, and Mr. Gage thinks a man can save more money in Memphis at \$1.50 a day than on a farm at 50 cents, with a house furnished; but the labor is harder in the city. He thinks the continuity of employment is about the same in either case. (494.)

Mr. BALCH, of Arkansas, finds that when a young negro is able to read and write and cipher he wants to go to town and shine shoes or get a position as a servant; many do not get employment and go to the bad. Mr. Balch thinks the farm is the place for the negro to get ahead; he has a better chance than the white man, because he is not expected to spend as much time and money in keeping up a position in society, and his wife and children work in the field. (497, 498.)

Mr. REDDING says the man who works on the farm can succeed only by producing something. Professional and business men in the city may live mainly by their wits, without producing anything or giving value received for what they get, largely by getting the advantage in trade, but the farmer can not get much the advantage of his laborers because they are already at handpan. (450.)

4. *Earnings of capital in agriculture.*—Mr. BRIGHAM believes that the earnings of capital in agriculture are from one-half to one-third less than in other pursuits. He does not believe that they average above 2 or 3 per cent, taking account on the one hand of the products used by farmers themselves, and on the other of their work. (14.)

Capital employed in agriculture does not seem to Mr. AGER to yield nearly as much profit as capital invested in other business. Capitalists seem to prefer bank-

OLVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

ing, etc., to investing in farms. Mr. Ager would rather have his capital invested in a farm than anything else, because he can manage it. Many farmers fail, but Mr. Ager does not believe the proportion of failures is as large as in mercantile business, where it is said to be 90 per cent. One trouble is that the farmers like to have their sons and daughters dress well and have as good horses and carriages as those in other business, and farms are often mortgaged for that purpose. Thirty per cent of the farms of Maryland, including many which were unencumbered 20 years ago, are now mortgaged. (110, 111.)

Mr. NORRIS thinks the earnings of capital in agriculture are not a quarter as great as in banking or mercantile pursuits, though taking the last 20 years as a whole perhaps as many have managed to live in agriculture as in any other business. (325, 326.)

Mr. WILSON, master of the Illinois State Grange, thinks the earnings of capital in agriculture are less than in other lines of business. (247.)

Mr. GEORGE, of Chicago, thinks the earnings of capital invested in agriculture are less than the earnings of capital invested in other industries. He estimates the average net earnings of capital in agriculture at 3 per cent. (221, 227.)

Mr. HANLEY says that grain and cotton, the great natural crops of the United States, are raised at a loss, as compared with other industrial occupations, because of a lack of proper legislation, and of organization and intelligent action on the part of farmers and workmen. The farmer is growing poorer each year. (274, 287.)

Mr. GREELEY, of South Dakota, believes that small investments in agriculture pay at least as well as anything else he knows of, and are safer; but that this is not true of investments in large farms by inexperienced men who farm them out. Mr. Greeley adds that the average farmer is determined not to count what he gets except the cash for the crops he sells in town; he does not reckon what he retains for home consumption. Reckoning these products and rent, etc., agriculture exceeds other occupations, and for certainty of returns it greatly surpasses the average business investment. When a farmer has for his family the best and freshest of all the land can produce, rent, livery, water, and sometimes fuel, he would be doing much better than many city people if he were not able to show any addition to his bank account; and this also any farmer who understands his business should be able to do. The certainty and permanency of his position should also be taken into consideration. (934.)

Professor DAVENPORT says profits from land will of course not compare with the profits of an eminently successful merchant, but the investment in land is more in the nature of a permanent investment and some income is certain. The farmer is not likely to lose his capital or impair it except by bad management, while some merchants lose all their capital very quickly. There are many excellent families with 80 acres of land who live successful lives, dress comfortably, and educate their children, and leave the sons better off than the fathers were at the start. Either we must reckon fairly large pay for the farmer's time, or a pretty large return on the capital invested, or else reduce the expense of living to a very small amount. Professor Davenport says he has never seen a student who has appreciated the value of landed possessions to a family. If a family can stay upon the land for 4 or 5 generations it becomes a power in its locality. (265, 266.)

Mr. HOLMES testifies that the agricultural products of the United States in 1889 were reported by the Eleventh Census to be worth \$2,500,000,000. The general opinion is that this statement is too low. It is doubtful if farmers in reporting the value of their products have included their living. The farmer probably omits his garden, which is worth \$25 or \$50, and certain farm products. On the other hand, there may be a duplication, because he may include so many bushels of corn, and also the steers fattened in the corn. Mr. J. R. Dodge, formerly Statistician of the Department of Agriculture, estimated the value of farm products in that year to be about \$3,500,000,000. Using the census figure, however, Mr. Holmes finds that the products were distributed as follows: Wages of agricultural laborers, \$645,500,000; commercial fertilizers, \$38,500,000; interest on mortgages, \$76,750,000; interest on crop liens, estimated at the rate of 40 per cent on the debt, \$120,000,000; taxes (estimated), \$116,666,000. Allowing theoretical interest on the remainder at 7.7 per cent, the average rate for farm mortgages in 1890, there remains only \$410,000,000 to be divided among nearly 5,500,000 farmers, giving them only \$6.33 a month as wages. On the other hand, allowing wages at the rate of \$22.61 per month would exactly absorb the remainder; thus it appears that allowing interest to the farmers on their farm capital, they earn substantially no wages, and allowing them no interest, they receive but \$22.61 a month as wages. (154.)

Dr. CROWELL submits a table compiled by Professor Emerick from the census of 1890, showing that the product of agriculture for each worker was only \$290, while

the product per capita in manufactures was \$893. This is declared to be a decisive argument in favor of moving to the city, so far as general averages are concerned. (338.)

New England.—Mr. STOCKWELL presents the results of an investigation by the Connecticut labor commissioner in 1888. The accounts of 693 farmers showed a total capital of \$3,810,742; the total receipts, including products consumed, \$707,153; expenses, including products consumed by the family, \$690,990; net profits, \$16,163, or, including the value of products consumed, \$143,325. (892.)

New Jersey.—There were in 1890 in New Jersey 30,288 farms of an average size of 86 acres, the total capital invested amounting to nearly \$184,000,000. Mr. DYE believes that the earnings of capital in farming are less than they were 40 years ago, and very much less than those of other lines of business. He quotes from an article by Dr. George H. Cook, which states that in 1870 the agricultural capital in New Jersey was \$265,000,000 and the value of agricultural products only \$46,000,000. In 1880 the agricultural capital had decreased to \$214,000,000 and the value of products to \$29,000,000. The capital invested in manufactures, on the other hand, was only \$80,000,000 in 1870, and the products \$169,000,000, while in 1880, with a capital of \$108,000,000, the products were \$254,000,000. (90.)

Mr. Dye believes, however, that with improved methods of fertilization and of cropping a farm can be made to pay fairly well in New Jersey at present, especially since the original investment, owing to the low price of land, is so small. (92.)

Mr. COLES, of Salem County, N. J., testifies that at the price at which farming land can be bought in that part of the State, farming, with careful attention and close economy, is fairly profitable. The farmer can live fairly well and pay the interest on the purchase price, and perhaps work off the principal a little at a time. The rate of interest is 6 per cent. (129, 130.)

Ohio.—Mr. MILLER thinks that for a period of years the condition of the Ohio farmer was as good as that of the merchants and manufacturers, but that at the time of his testimony (1900) it was perhaps not as good, because the conditions were then very favorable for the manufacturer and dealer, and very unfavorable for the Ohio farmer because of the loss of crops and the low prices prevailing for some agricultural products. (614, 615.)

Illinois.—Mr. WILSON says it requires just as good a man to run a 160-acre farm as to run any other business, but the grain farmers of Illinois, while they have made a living and educated their children, have, as a class, made very little money of late. (251.)

North Dakota.—Mr. BUDGE says that taking into consideration the price at which lands were bought in North Dakota, the capital invested in agriculture does very well as compared with investments in other lines, but the land which he bought at from \$2.50 to \$5 an acre he now considers worth from \$25 to \$40 an acre. (848.)

Mr. PROM, a banker of Milton, N. Dak., thinks agriculture is much more profitable than any business enterprise conducted in North Dakota. The banks pay 20 per cent dividend, but Mr. Prom's farm, which is worked on shares by tenants, pays better than that. (791.)

Mr. Prom adds that the farmers of the Red River Valley in North Dakota do not think it best to leave the farm and go into anything else; they stick closely to the farm. Those who came there in 1882 and 1883 are as independent as any rich man; they do not want all the luxuries, but they are progressing. (794.)

Kentucky.—Mr. NALL testifies that the people of Kentucky think capital employed in agriculture is not as profitable as that employed in other lines of business, and he is inclined to their way of thinking. (809.)

Georgia.—Mr. STEVENS states that of the \$435,000,000 of taxable property in Georgia \$185,000,000 are invested in agriculture, including the value of the lands, \$120,000,000; live stock, \$22,500,000; farm implements, \$5,250,000, and household furniture, \$16,250,000. The income from the farms is estimated for the year 1900 at \$83,179,000, or 50 per cent gross or 8 per cent net. The income is made up chiefly from cotton and corn, with smaller proportions, in the order named, from peaches, sirup, rice, apples, vegetables, sugar, and tobacco. (914.)

Generally speaking, Mr. Stevens says, well-managed Georgia farms pay from 8 to 10 per cent on the capital invested. The earnings from capital thus invested compare favorably with the earnings of mercantile and other similar lines of business. (915.)

Alabama.—Mr. POOLE intimates that the plantations of Alabama pay from 10 to 15 per cent on the investment. (922.)

Louisiana.—Dr. STUBBS, of Louisiana, concludes that as the banks lend the farmers money at a fair rate of interest, farming must be better than banking in a small way. It is certainly better than Southern railroads, most of whose stock is below par. The Illinois Central pays a dividend (Dr. Stubbs thinks 5 per cent), but he

does not think any of the Louisiana farmers could be induced to farm with as little as 5 per cent income. (782.)

5. Reasons for a low rate of profit.—Dr. CROWELL explains the comparatively low earnings of capital in agriculture substantially as follows: In agriculture the competitive principle governs prices, but in manufacturing, after a certain limit of competition is reached, the inevitable result is combination, which has come about on account of the difficulty of distributing or marketing the product so as to get an even, continuous return on the capital. In agriculture prices tend to remain near the cost of production, the lowest level of efficiency of capital being found in agriculture. Manufacturing interests, after they have spent their competitive energy, tend to combine and organize with a view of controlling production in the interest of more regular prices, and thus tend toward the maximum of return on capital and reward for labor. The principle that governs the distributive system, also, is the principle of combination. When the Eastern farmer produces for Europe and the Western farmer for the East, the distributive feature enters and the great profits arising are a temptation for labor and capital to go into that activity; so the distributive system increases until it grinds heavily upon the community, especially if it is favored by legislation, as, for example, by export premiums. Dr. Crowell says we seem to have arrived at a condition where the distributive system is a very important feature, and it seems to him that the wise line of policy to follow is to equalize the opportunities of capital in distribution and in production. (339.)

Dr. Crowell explains that the farmer is governed by the law of diminishing returns; that is, for every additional unit of capital and labor he will get less than a proportionate return in product. In manufacturing the law of increasing returns generally applies. Thus the farmer is limited by nature as the manufacturer is not. On the other hand, land which was supposed to have reached the point of diminishing returns may by some discovery or advance in agriculture be made to produce a much higher return than under the old methods of cultivation. (340.)

Mr. HOLMES explains the small income of farmers and farm laborers by saying that they do not produce enough wealth. The agricultural product in 1889 was only \$293 for each farmer and farm laborer. In the South Atlantic States it was only \$177; in the South Central States, \$211; in the North Central States, containing most of the great corn and wheat States, where machinery is much more in use than in the South, \$362; in the North Atlantic States, which are States of more dense population and diversified agriculture and better local markets, \$389; in the Western States, including the Pacific States, \$519. Mr. Holmes believes that this highest product of agricultural wealth in the Western States permits the comparatively high rate of farm wages in that part of the country. A larger value is produced in manufacturing than in agriculture, namely, \$896 per worker, and wages are very much higher in manufacturing industries than on the farm. (155.)

6. Disrepute of agriculture explained.—Professor DAVENPORT explains the feeling that agriculture is a degrading or menial occupation on historical grounds. During and after the Roman Empire, he says, agriculture was largely an occupation of the conquered and enslaved nations, so that there is a kind of inherited feeling that gentility goes with government and professional positions. Again, the farmers themselves have accepted and fostered the idea that agriculture is an inferior calling, and the feeling has been fostered sometimes by local politicians, who have informed the farmers that all the other occupations were combined against them. (258.)

Mr. REDDING, director of the Georgia Experiment Station, says there is never any disposition to look down on agriculture in the South, but laboring people associate the idea of field labor with negro labor, because most of the laborers in the lower part of Georgia and South Carolina are negroes, and if a white man went into the field he would have to work with them. (449.)

7. Debt of the city to the country.—Mr. POWERS says there are many debts of the city to the country. There is a constant movement of men and wealth to the city, exhausting the farm wealth. If they do not give something back to the sections from which they come, these sections will be pauperized and degraded. Their ability to make money must be kept up as the fertility of the farm is kept up. The money earned on the farm which has been moved to the city must be taxed to give a legitimate income back to the farm to expend for country schools and roads. (185.)

VI.—AGRICULTURAL EDUCATION AND RESEARCH.

A. In foreign countries.—Dr. TRUE, director of the Office of Experiment Stations of the United States Department of Agriculture, calls attention to a great world-wide movement for the organization of technical education in agriculture and scientific research along agricultural lines during the last half century. Among for-

eight countries the movement has reached its highest perfection, in some respects, in France, Germany, and Belgium, where the system of agricultural education includes schools of various grades, from the university to the elementary school. Russia, Australia, and Japan are developing quite complete system of agricultural education and investigation. Egypt has at least one very well organized agricultural college, in connection with which experiments are conducted, and the Sultan of Turkey has called upon the Secretary of Agriculture to recommend an expert to advise him how to organize agricultural education and experimentation in the Turkish Empire. The great commercial nations with which the United States is coming more and more into competition are every year increasing their efforts to perfect their system of agricultural education and investigation, and the United States can not afford to be behind the rest of the world in this respect. (138.)

1. **Germany.**—Mr. POWERS says Germany has led the world in bringing out all the possibilities of the soil through agricultural schools and experiment stations. This has been a monumental work of great benefit to German farmers. (177.)

2. **Great Britain.**—Dr. TRUE says Great Britain has no thoroughly organized agricultural education or experimentation, though there are a few agricultural colleges, and in recent years grants of money have been made to a number of institutions. Reports of the experiment stations of France, Germany, and Belgium are being constantly translated and made available to the English farmer, and the experiment station at Rothamsted, England, which has been at work over 50 years, has also given him much valuable information. The great societies of agriculture in England and Scotland have also had an important part in the development of British agriculture; in some things, however, the British farmer has not been able to hold his own. The farmer of Denmark, who, with the help of the Government, has organized the business of dairying on a scientific basis, is able to go into the English market with butter, and to some extent drive out the Englishman. Dr. True also explains the sale of Canadian cheese in England as a result of the very systematic and thorough work in agricultural education and investigation carried on in Canada, where the reports of the experiment stations are widely disseminated. (144, 145.)

Dr. WILEY says Sir John Lawes has given practically his whole private fortune, amounting to over \$500,000, in trust to continue the experimental work in agriculture which he conducted for 60 years in conjunction with Sir Henry Gilbert. Dr. WileY thinks this is the only instance in which a man has given his entire fortune for such a purpose without any hope of pecuniary gain. (643.)

3. **Seed control stations on the Continent.**—Dr. WileY says every European government (especially Germany and Russia, and to a less degree Austria and France) maintains seed control stations where experiments are conducted. The German seed control stations are about 15 in number, devoted entirely to determining experimental methods of improving the quality of beet and other seeds. (642.)

B. American agricultural colleges.—1. **History.**—Dr. TRUE says the agricultural colleges are organized under the land-grant act of 1862, which granted each State and Territory 30,000 acres of land for each Representative or Senator in Congress, the proceeds from the sale of which were to constitute a fund for the maintenance of colleges in which agriculture and the mechanic arts should be taught. Before 1862 only a very few States had agricultural colleges. Michigan was the first State to establish such a college. Maryland, Pennsylvania, and other States had made some movement in that direction. (139, 144.)

2. **Statistics.**—There are land-grant colleges, Dr. TRUE says, in all the States and Territories except Alaska. Some of the States have separate institutions for the colored people, so that the total number of such institutions in 1898 was 64, of which 61 maintained courses in agriculture. Their resources of funds, lands, buildings, and equipment were valued at more than \$53,500,000, and their incomes amounted to more than \$6,000,000. The value of the addition made to their buildings and equipment in 1898 was estimated at \$2,800,000, paid for, in large part, by State appropriations. There were 2,611 persons teaching in these institutions, and the total number of students as 31,658, of which number 4,181 were in agricultural courses. (140.)

3. **Character of work.**—Dr. TRUE says the agricultural college at Amherst, Mass., is the only purely agricultural college in this country. In 27 States and Territories the land-grant colleges are organized as agricultural and mechanical colleges. In 20 States they are the State universities, in which there is a department or school of agriculture. In all these institutions there is the regular college course in agriculture, shorter courses, commonly of 2 years' duration, and special courses in dairying, etc. There has been a great tendency of late years toward specialization. (139.)

Mr. HALE declares that the Government aid to agricultural colleges is misapplied. When the grant was made most of the States had not begun to realize that farming was anything more than digging something out of the soil. They turned the grant

over to their classical institutions, the management of which took no interest in agricultural education. Michigan was one of the States that saw the need of scientific instruction in agriculture. Mr. Hale declares that the Michigan Agricultural College is a marvellous success, and that Kansas and some other States have done exceedingly well. In general, the idea has been that if a boy or girl could get a little classical education he would be enabled to get a living without working. Mr. Hale declares that Congress ought to see that the money is used as it was intended to be. (386.)

Professor DAVENPORT says it was 20 years before the agricultural colleges succeeded to any reasonable degree in teaching the principles involved in agriculture. They first had to be discovered. At first the attempt was simply to recite the practice of the country as it existed, but there has developed an immense literature in agriculture, and there is now enough to base a strictly scientific course of study upon. The universities, where the educational problem was complex, were longer in recognizing the proper basis upon which agriculture should be studied than were the colleges, which had but one problem to work out; but of late quite a number of universities have caught the idea that agriculture is a thing to be studied by itself, and have put in very strong departments of agriculture. Students have responded about in proportion to the value of the instruction. Agriculture and the mechanic arts are the new studies in universities. Since the founding of the agricultural colleges and State universities we have gone through a most active period of mechanical industry, and the problems of mechanics being simpler than those of agriculture and capable of mathematical demonstration, they are more quickly worked out; and so in nearly all the schools the mechanic arts develop more rapidly than agriculture, which involves the nicest questions of chemistry, botany, biology, physics, and geology, as well as economics. It is only within a few years that really good instruction has been given in agriculture. In the end the universities ought to do better work in agriculture than the colleges, because the environment is better and the associations freer. Professor Davenport does not think there is any prejudice in the universities against agriculture. There is a growing respect for the subject. (259-261.)

Mr. MCKAY, a trustee of the University of Illinois, says that many of the land-grant colleges have developed into real universities, and have very largely met the local demands for instruction. When the institutions were established there was not much demand for scientific instruction in agriculture, especially in the Western States, because by simply turning over the soil of the prairies and cultivating it very indifferently a man could raise a crop of 50 or 60 bushels of corn to the acre. The time has now arrived when it is necessary that each acre of land should produce the best possible results, and there is arising a demand for scientific agriculture. Mr. McKay believes that these institutions will meet the demand. The board of trustees of the University of Illinois have asked for large appropriations for the college of agriculture. (534.)

Dr. TRUE says the general plan of teaching in agricultural colleges and schools of this country has not been well organized. The Association of Agricultural Colleges and Experiment Stations is studying the methods of teaching agriculture with a view to their improvement. Dr. True does not think, however, that the best plan is to have the students spend a considerable part of their time on the farm. The farm should be used as a laboratory is, though incidentally the student will get a certain amount of practice from this use. The aversion of farmers to "book learning" is a very great obstacle, but the number of farmers who read and profit by the literature available to them is increasing yearly. (145.)

4. *Agricultural colleges in various States.*—*Vermont.*—Mr. SPEAR testifies that the Vermont Agricultural College is gradually gaining in students and effectiveness, and is regarded with good favor by the people of the State. During the past few years there has been a dairy school, lasting a month or 6 weeks each winter. (404.)

New Jersey.—Mr. DYE says the New Jersey Agricultural College owns a farm, dairy, etc., which are made self-supporting, and on which valuable experiments are being made. Farmers are invited to visit and inspect the farm, and numerous farmers cooperate with the institution by conducting experiments on their own farms. (89.)

Ohio.—Mr. MILLER says the Ohio State University has short, intermediate, and long courses in agriculture, as well as veterinary, dairy, and other special courses. Degrees are conferred in the full agricultural course, in the veterinary course, and, perhaps, in the dairy course. Some years ago there was general complaint against the State University, which is the successor of the old Agricultural and Mechanical College, but recently the College of Agriculture has been so improved and enlarged that it is generally satisfactory to the people and is growing in patronage, though it is not yet well patronized for a State with the agricultural population of Ohio. The expenses have not been reduced to so low a point as at many of the other institutions in the State, and this discourages the attendance of the poorer farmers' sons.

Not much attention has been given to the dormitory facilities. The students who seek employment on the university farm are paid a certain amount an hour for such work as there is to do, and some students have been self-supporting. The classics overshadow the agricultural department, however. Perhaps the greater number of those who enter the agricultural classes change their course and graduate in one of the other departments, drifting into the professions. (609, 610.)

Illinois.—Mr. MCKAY testifies that the University of Illinois consists of colleges of agriculture, science, engineering, arts, law, and medicine. He thinks the College of Arts has always had a larger number of students than any of the others, but there are very few students studying Latin and Greek. (535.)

Professor DAVENPORT says we should do better in America than the European agricultural school, which aims chiefly to train students in methods of practice. We must turn out well-trained citizens. At the University of Illinois a man graduates in agriculture when he offers the same number of credits that would entitle him to graduation from any other course. One-third of these must be in technical agricultural subjects, one-third in science, and the other third from anything the university offers. In practice the students generally take more agriculture than is required. (284.)

North Dakota.—Mr. FROM, of Milton, N. Dak., says there is an agricultural college at Fargo, which does much good in that State. There is a growing interest in the education of the farmer in North Dakota, and the farm boys are getting a better education. Mr. From thinks the improvement has a tendency to keep the boys on the farm and make farm work more interesting. President Hill, of the Great Northern Railroad, sends a train through the country during the summer and invites the farmers to ride over to Fargo to visit the Agricultural College and return without any charge. This is taken advantage of by the farmers, with the best results. (790, 791.)

Mr. BUDGE testifies that a good many farmers' sons go to the agricultural college during the winter. There are probably 300 students. A great many young men who have farms go to the college to study up on farming during the winter, when they have not much to do. Some also go to learn how to run thrashing machines, etc. Men 18, 20, and 26 years of age go there and take the course in farming; then there are longer courses for the boys who go through. (847.)

South Dakota.—Mr. GREELEY says the South Dakota Agricultural College has what is called an agricultural course, but he regrets that there is a great tendency in most agricultural schools to make universities of them and forget the practical—to make scholars and not farmers of those who go there. (931.)

Minnesota.—Mr. GREELEY adds that the agricultural college in Minnesota is having the same trouble that of South Dakota is, but not quite so much so, principally because the agricultural school and the State university are together, as is the case also in Nebraska, while in South Dakota and other States the university is in one town and the agricultural school in another. (932.) (See also *Separation from universities*. VI B 8, p. CLXVII.)

Mr. POWERS testifies that President Hill of the Great Northern Railway brings every year, from every county along his road in Minnesota, and sometimes from Dakota, two persons from every township to Minneapolis, transportation free, to stay three days in the city, with the understanding that they shall spend one day at the State School of Agriculture and Experiment Station. Mr. Hill says this is not philanthropy, it is business; and explains that the profit of his road can come only from the added prosperity of the farmer, which can come only by a higher knowledge of agriculture, and improved methods. For several years he has brought the equivalent of 10 train loads of people a year a distance of from 150 to 300 miles. A great many of these will be interested in sending their boys and girls to the agricultural school. (183.)

Maryland.—Mr. AGER, master of the Maryland State Grange, testifies that the mechanic arts, horticulture, and dairying are taught at the Maryland Agricultural College, as well as agriculture. He thinks more of the pupils are educated in the classics than for agriculture. (107.)

Kentucky.—Mr. NALL testifies that the Kentucky Agricultural College is getting to be very well supported by the farmers. The number of students is about 360, of which number 7 take the agricultural course alone. (812.)

North Carolina.—Mr. WHITE says there is an agricultural and mechanical college at Raleigh for the whites, and one on a much smaller scale for the colored people at Greensboro. (425.)

Mr. GRAHAM criticises the equal division of the agricultural and mechanical college fund of North Carolina between the two races, arguing that there are twice as many whites as negroes in the State, and that the same amount of money does not

get the same number of teachers in the white college as in the colored college, because the teachers are of higher grade. (439.)

South Carolina.—Mr. HAMMOND says that Clemson College is an excellent technical school, with professors and a full equipment of laboratories and workshops, including a large and complete technical school. It is supported partly by the State, and partly by a fund created by the General Government. There is also a negro school at Orangeburg supported in the same way. Mr. Hammond does not think that the graduates of the agricultural colleges as a rule go back to farming. They go into all sorts of positions where knowledge of chemistry and engineering is required. Actual instruction in agriculture, if it is to be practically applied, must be given in the common schools. (824, 830.)

Georgia.—Mr. REDDING testifies that there is a State agricultural college in Georgia, but few students take the agricultural course. (451.)

Mr. BROWN testifies that the money devoted to the agricultural and mechanical college in Georgia has largely been used in teaching Greek and Latin and similar subjects. Nevertheless a beginning is being made toward industrial education. There are separate industrial schools, supported by the State, for white boys, white girls, and colored persons. (64.)

Mr. HALE testifies that the State University of Georgia, which receives aid from the Government under the acts of 1862 and 1890, is a classical institution, but aims to give enough agricultural and mechanical education to be enabled to receive the money. Agricultural education is not magnified as it ought to be. The leading agriculturists and the State Agricultural Society have agitated the question of making the agricultural college a distinct school, but the graduates of the university are in the law offices and newspaper offices, and control public opinion. Mr. Hale says there are two or three other technical institutions of a moderate degree of efficiency in Georgia. (385, 386.)

Alabama.—Mr. POOLE testifies that the Agricultural and Mechanical College at Auburn, Ala., has been in existence 30 years. Agriculture is taught in all its branches. Tuition is free, except for incidental fees of perhaps \$10 or \$12 a year. An experiment station is connected with the school.

There are also in Alabama 9 district agricultural colleges, 1 in each Congressional district, drawing \$2,500 a year from the State Department of Agriculture, which contributes also to 2 colored agricultural schools—Booker Washington's, at Tuskegee, and another near Montgomery under Professor Patterson. (920.)

Louisiana.—Dr. SUMMS testifies that the 2 agricultural and mechanical colleges of Louisiana, for white and colored students respectively, were established under the land-grant act and the Morrill bill granting \$25,000 (\$15,000 at first) to each State and Territory. The college for whites is associated with the old Louisiana State University at Baton Rouge. It is very prosperous, having nearly 400 students, males exclusively. The university has a literary and scientific course, covering general science, as well as agricultural and mechanical subjects. It also includes the Audubon Sugar School. (779.)

5. Special schools and special courses.—*New York State College of Forestry.*—Professor FERNOW, director of the New York State College of Forestry, says that this college was established in 1898, by act of the legislature of New York, for two objects: to educate foresters, and to make a demonstration of practical forest management on a tract of timber land in the Adirondacks. It is an integral part of Cornell University. The course of instruction is one of 4 years. Four students were registered the first year, 17 the second, and 26 the third. Certain courses in the college have been taken by much larger numbers of students from other departments of the university. The students will find employment after graduation with forest commissions of New York and other States, with the United States Bureau of Forestry, and with lumber firms and managers of large estates which include forest properties. Probably, also, other colleges of forestry will be established and will need teaching forces. (1000, 1001.)

Dairy school, Wisconsin.—Dr. TRUE testifies that the special dairy school at the University of Wisconsin has already (1899) sent out about 800 trained butter and cheese makers, and has taught between 1,000 and 2,000 young men butter making on the farm as distinguished from that in the creamery. There is also at this institution a short course in agriculture, having 190 students in 1898-99. Professor Henry, dean of the college, says that places have been found on farms in this one year for more than 50 young men, who got from \$2 to \$10 a month more because of their special training. (139.)

Audubon Sugar School.—Dr. TRUE says a school for training sugar experts has been in operation a number of years at Audubon Park, New Orleans, in connection with the experiment station, and more recently at Baton Rouge, in connection with the State university, which has proved useful and has received financial support from the Sugar Planters' Association. (139, 140.)

Dr. STUBBS says the Audubon Sugar School, which was started under his direction, was established by the sugar planters of Louisiana, and after 4 or 5 years the State adopted it. There is a 5-year's course. The students spend 6 months in studying the sciences and in the workshops of the Agricultural and Mechanical College; then for 3 months in the year they work practically in the sugarhouse, the sugar fields, and the laboratories of the sugar experiment station. Every boy who attends the school is required to plow, plant, hoe, ditch, cut cane, run the boilers and machinery of the sugarhouse, and do everything that is done on the place. Dr. Stubbs has kept a millionaire's son on a 4-mule plow while the thermometer was ninety-odd degrees in the shade. (778, 779.)

Dr. Stubbs says there were a dozen Cubans in the sugar school when the war broke out. Science knows no political boundaries, and when the school was first opened the question arose what should be done with applications from foreigners. The people decided that all they could do was to charge an increased tuition, which was done until the State took charge. The State law prohibits any charge at all for any instruction the State gives, and hence foreigners are educated at the sugar school without payment of fees. (780.)

6. Occupation of graduates.—Dr. CROWELL's observation leads him to believe that pupils instructed in agricultural colleges, etc., do not go back to the farms, and for that reason he thinks distinctively agricultural institutions have not yet found their normal function. (337.)

Mr. BRIGHAM says that unfortunately a considerable proportion of the farmers' sons who are able to go to college desire to take up some other work than farming, though this tendency is becoming less marked. (12.)

Mr. WHITNEY remarks that few of the young men who go to college attempt to fit themselves for farm work. He instances the small number of students who have taken the agricultural course at Yale University, which has had a permanent endowment for agricultural education. He also says that at Harvard, which has both an agricultural and a technical school, there is a much greater attendance at the technical school, and also in the classical college, than in the agricultural course. (868.)

Mr. HALE knows of a number of successful farmers in Massachusetts, Connecticut, Michigan, and New York who are graduates of agricultural colleges. He says the graduates of these colleges far outstrip other farmers, if they have a love of the soil and the same business ability. (387.)

Mr. NORRIS says many young men are getting much benefit from the agricultural courses at Cornell, especially the short courses of 10 or 20 weeks in dairying, fruit growing, and practical agriculture. As a rule, he thinks they are content to go back to the farm, but as farmers some young men would be complete failures, "because they never were born that way." A man will not be a success in anything he does not like. Mr. Norris thinks every man should be allowed his natural inclination; if he has an eye for mechanics, he ought to take a course in that line. (324.)

New Jersey.—Mr. DYE says that a very small proportion of the graduates of the New Jersey Agricultural College go back to the farms. (88.)

Mr. COLES, of New Jersey, testifies that some of the students of the agricultural college return to the farms, and some have gone on to a higher education and found more profitable business. The influence of the agricultural college on agriculture is felt more through the dissemination of information among farmers than in the education of farmers' sons. (126.)

Ohio.—Mr. MILLER testifies that the graduates of the College of Agriculture of the Ohio State University go back to the farm as a rule. Among them are some of the very best lecturers and workers in agricultural lines. (610.)

Michigan.—Professor DAVENPORT testifies that the Michigan Agricultural College, which graduated its first class in 1861, took a census of its graduates 25 or 30 years after its establishment and found that a little more than 50 per cent of them were in agriculture. A careful study was made of the proportion of graduates of purely technical schools, such as lawyers, doctors, and ministers, who follow through life the calling they were educated for, and it was found to be below 50 per cent. Professor Davenport has known many men who came to the college without any idea of going onto the land, because it was a cheap course to take, who afterward did go upon the land. It takes capital to own and operate land, and is more difficult to acquire a farm than to go into a profession, so there has been a great tendency for the graduates to teach school for a time or do something else in which they could make more money than by doing ordinary farm labor. The Michigan Agricultural College found that of the 50 per cent not on the land, a large proportion of the graduates of long standing were landowners, and that nearly all the recent graduates looked forward to owning land as soon as they could afford it. There is now a tendency for young men who are up in agriculture to rent farms. (261.)

Illinois.—Mr. MCKAY testifies that the percentage of those taking an agricultural

course in the University of Illinois who have gone back to farming has been very small. A young man taking a 4 years course in the university obtains a fairly liberal education. If he takes the regular course in agriculture, he gets more than simply the technical agricultural subjects; he has considerable literature, modern languages and a good knowledge of chemistry, physics, and biology. A number of the graduates are now deans of colleges of agriculture, or professors of agriculture; some are directors of experiment stations. They went into these positions because they could earn more than they could on the farm. (535.)

Professor DAVENPORT explains that the teaching of agriculture in the universities is more technical than in the colleges of agriculture, and that students do not take the course unless they expect to go upon the land. The agricultural students at the University of Illinois will all go upon the land, except an occasional one who is picked out for an instructor somewhere. (262.)

Minnesota.—Mr. POWERS says boys are sometimes educated just enough to take them away from the farms, and the agricultural colleges sometimes educate them in wrong lines. The Minnesota School of Agriculture, however, is educating them to stay at home. They go back and become important factors in the elevation of farmers, spreading abroad a knowledge of the science of agriculture. None of the other western institutions have so large a proportion of graduates who go back to the farms. (172, 183.)

North Dakota.—Mr. BUDGE says a great many of the graduates of the North Dakota Agricultural College leave the farms and seek the professions. Some go from the agricultural college to the university, and some go to the University of Minnesota. The university boys are a little older than the agricultural college boys. The older students at the agricultural college study for the improvement of their own farms, but the young boys go there because they can get in when they can not get into a college; then in a year or two they go to the higher schools. (847, 848.)

Kentucky.—Mr. NALL says a good many of the graduates of the Kentucky Agricultural College return to the farms, and they make very intelligent farmers. They are the entering wedge for better farming in Kentucky. Quite a number have gone into other pursuits. (812, 813.)

Audubon Sugar School, Louisiana.—Dr. STUBBS says the Audubon Sugar School has graduated quite a number of young men who are now filling positions wherever cane sugar is grown—probably 15 or 20 are in Hawaii, including the director of the experiment station there. The director of the experiment station in Queensland, who was formerly one of Dr. Stubbs's assistants, went out there on a 5-year contract at \$15,000 a year, to teach sugar growing and manufacture. Another graduate and former assistant is director of the experiment station of the Hawaiian Planters' Association, at Honolulu, getting \$5,000 a year and expenses. The boys are doing well everywhere. They have also added to the Louisiana sugarhouses, a fair proportion of which are run by the graduates of the school. A dozen or more are in Cuba; others are in Mexico, Porto Rico, the Danish West Indies, French Martinique, Guadeloupe, and Mauritius. (779, 780.)

Wholesome influence of college-trained farmers.—Dr. TRUE says agricultural colleges are sending out every year young men thoroughly trained in agricultural lines whose influence will be very great in promoting the progress of agriculture. (140.)

Professor DAVENPORT testifies that the graduates of the Michigan Agricultural College engaged in agriculture have been much more successful than the average farmer, and that recent graduates especially have become centers of better methods in their own communities. The sentiment against "book farming" has entirely changed during the last decade, and now if a man knows a thing, the farmers are glad to learn it from him. (262.)

7. *Beneficial effect of the agricultural colleges upon agriculture.*—Mr. STOCKWELL says the State agricultural colleges are doing a grand work in sending out lecturers and teachers by example, as well as in institute work. There has been a great advance within 20 or even 10 years, largely due to the technical and experimental education in agriculture. (887.)

Mr. DYER says the various agricultural colleges in this country have done much to lay the foundation for better farming. It was about 1840 that chemistry began to be applied to the study of agriculture, the needs of soils, etc., and the effects have been very beneficial. The laboratory discovers principles which are of practical importance to the farm, but the chemical analysis of soils to determine the proportion of plant foods which they contain and the needs of fertilizers is not in itself sufficient; it must be accompanied by careful experimenting with different crops and fertilizers. This is being done with very beneficial results by the State experiment station in New Jersey and by similar stations elsewhere. (88, 89.)

Mr. POWERS says the agricultural colleges of the West are doing a great work. He is satisfied that the work of the agricultural colleges and schools in the West is add-

ing as much as or more than any single factor to the prosperity of the farmers. (183.)

Professor DAVENPORT thinks the support of agricultural colleges is the best investment of money the Government ever made, considering the good to the farmers, the maintenance of fertility, the upbuilding of agriculture, and the cheapening of products which result. He says, the tendency to support agricultural colleges is much greater than formerly. (262.)

8. Proposed changes in organization and courses of study.—*Separation from universities.*—Mr. BRIGHAM considers that agricultural and mechanical colleges should be kept entirely distinct from other universities. In many cases the State universities have secured funds from the State and national governments, nominally for education in agriculture, and have spent them in teaching the classics and similar subjects. In the separate instruction there would be more likely to exist a sentiment as to the honorable nature of work and a pride and enthusiasm for agriculture. (13.) (See also VI B 4, Minnesota, p. CLXII.)

Modification of curriculum.—Mr. BACHELDER says that the various agricultural colleges in New England devote relatively more attention to mechanical arts than to agriculture. A large proportion of the farmers' boys who go through the course enter other occupations and do not return to the farm. Mr. Bachelder believes that the courses should be so modified as to develop enthusiasm for agriculture and thus tend to raise the standard of farming and of rural life. (44.)

Domestic training.—Miss EMMA SICKELS, secretary of the National Pure Food Association and of the National Domestic Science Association, says that comparatively small opportunity is given for education in the normal, healthful vocations of life, such as the best methods of conducting a farm, a business, or a home. Education is designed to meet abnormal conditions, which are actually developed by the facilities provided for meeting them, while the means for best promoting normal conditions are neglected. This is especially true of women's work. The only opportunities for a thorough education lie in some profession or other field of men's work. It is easier for a woman to be a physician, a lawyer, or a chemist than to be a cook in the broadest sense of the word. It is easier to learn anatomy, botany, or astronomy than to learn the principles of combinations of food materials and the right use of foods. There is no place in which domestic science is taught in the systematic way in which almost every science is taught. For 20 years Miss Sickels has been trying to find an opportunity for making as thorough and systematic a study of the laws for the preservation of health as is afforded in the schools of medicine for its restoration, but has found no place in any school or university where the simple necessary rules of life are efficiently and effectually taught. (519.)

Miss Sickels says the agricultural colleges of Minnesota, Iowa, Ohio, Illinois, and Kansas (Professor Davenport adds South Dakota and Michigan) are now giving some attention to the preparation and use of foods, but they are handicapped by lack of system and lack of funds. Some uniform system should be developed applicable to all of them, and their reports systematized by the Department of Agriculture, as recommended by the subcommission on domestic science of the Senate Committee on Agriculture. The teaching of cooking in the public schools would naturally follow from this work in the universities. In 1899 an appropriation of \$15,000 was made for investigating the nutrition of food; but the investigations now made are almost solely as to a balanced ration, while in practical application the methods of preparation have the greatest value and importance. In most cases the use of stimulants is due to lack of nutritious food. Miss Sickels says there is a lack of text-books on this subject. (520, 521.)

Mr. Greeley thinks no girls' school, particularly a normal school, should ever permit a girl to go out from it until she is a thorough housekeeper and cook, well acquainted with plain nursing, and trained to regard these things as among the highest womanly accomplishments. (931.)

C. Primary and secondary schools.—**1. Need of practical training in farm work.**—Mr. WHITNEY criticises the agricultural institutions for not being satisfied to remain schools, but aspiring to the dignity of colleges and universities. Abroad, he says, it is much more frequent to see primary or high schools in agriculture in farming districts. A young man educated in such an institution is likely to be much more contented to follow agriculture than one who goes to a university, where the agricultural course is looked down upon by the other students and is supposed not to maintain the rigorous training that the classical and mathematical studies are thought to offer. It seems to Mr. Whitney that the opportunities are not presented to train people in the particular knowledge required in any line of agriculture. He thinks there is need for more agricultural schools and not for more agricultural colleges. The schools should be right out on the farm lands where the boys work. If

CLXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

such a school were established in an agricultural center like Lancaster County, Pa., under the splendid agricultural conditions prevailing there, and if boys could see the methods pursued and learn how to handle stock and crops, they would acquire information that would fit them admirably to take charge of estates or lands of their own elsewhere. If Mr. Whitney wanted to educate a young man to be a tobacco expert, he would send him to Florida, where the industry has been developed along really scientific lines by practical men. A man familiar with the details of the work, though not otherwise educated, will command a salary of from \$2,000 to \$4,000. (869, 870.)

Mr. GREELEY, secretary of the Board of Regents of Education of South Dakota, says the best agricultural school for a boy is to spend a year with a thorough-going up-to-date stockman and farmer, and to live in daily touch with first-class stock raising and farming. The nearer the agricultural schools can come to this the more successful they will be. (931.)

2. Existing schools of agriculture.—Dr. TRUE says there is connected with the University of Minnesota a School of Agriculture of high-school grade, organized separately from the College of Agriculture, and reporting in 1898 an attendance of 275 young men and 50 young women. Nearly all the graduates are said to return to farm homes. One branch of the institution is a dairy school, with an attendance of about 100 young men with some previous experience in butter and cheese making, who desire a more technical knowledge of the subject. A similar school has been started at the University of Nebraska, with an attendance (1899) of 60 boys, reported to be direct from the farm and with the intention of going back. Hampton Institute, Virginia, and Tuskegee Institute, Alabama, are developing agricultural courses along high-school lines. There is a school at Doylestown, Pa., under Jewish auspices, understood to be endowed by the Baron Hirsch fund, which has a farm school on the European pattern, the boys living on the farm and having practical instruction in agriculture. Dr. True also understands that the Miller Manual Training School of Virginia gives some training in agriculture in this way. He regards this as simply the beginning of a movement for secondary agricultural education, and believes that there is needed the development of secondary schools of agriculture in this country as they have been developed in Europe. (140.)

Glenwood School for Boys.—Mr. GEORGE founded the Glenwood School for Boys near Chicago about 1889, for the purpose of educating boys in agriculture. (224.)

Briarcliff Manor.—Mr. FLANDERS, of New York, says that a school has been established at Briarcliff under private auspices in the hope of doing something to turn the tide of young men from the city back toward the farm. It was an outcome of an investigation of the scarcity of farm laborers made by the New York Association for Improving the Condition of the Poor. (998.)

Hampton and Tuskegee.—Dr. TRUE says the education in agriculture at Hampton and Tuskegee is decidedly practical, though it has not gone very far. The experiment stations and agricultural colleges in the South are also teaching a great deal of value to the farmer. (145.)

Mr. POOLE says the advantages to the colored man of such schools as that of Booker Washington's are simply wonderful. Mr. Washington is a great man and doing a great work for his race. At the State fair at Birmingham in October, 1900, the agricultural and mechanical exhibit from the institute would have done credit to any college. Mr. Washington and his assistant, Mr. W. B. Counsel, encourage their pupils to go into agricultural pursuits, but that is done very little; young negroes take to the professions, especially preaching. Tuskegee Institute receives \$1,500 from the State department of agriculture, and certain other moneys from the public-school fund. (923.)

Mr. HALE thinks Mr. Washington is doing wonderful work. A number of very bright young men from Tuskegee have come to his fruit farm as tramp laborers looking for work. He found that they came to get a practical knowledge of a well-managed fruit farm, rather than for the wages. In some instances they have been disappointing, but as a rule they are satisfactory. (401.)

Calhoun Colored School.—Mr. DILLINGHAM says that Lowndes County, Ala., is a typical Black Belt county, selected by Mr. Booker Washington when the Calhoun School was started, about 1892. There is at Calhoun a sort of farm village, having at the center a graded school running from the kindergarten up to the primary and grammar grades, giving agricultural training for boys and domestic training for girls. There are 18 workers at the school, about one-third educated blacks from Hampton and the rest educated whites from the North. They are trying to build up a neighborhood with an institutional object lesson at the center, consisting of a farm, a home, a school, and a church. The school is under no denominational control, but is supported by voluntary contributions almost entirely. The students range in age from 5 to 21 years. Only 1 of the graduates has disappointed the teachers; the others all promise well. Some are buying farms, and that is the ambition of all; one is a level-

headed preacher in the neighborhood. They are trying to go on with their education and to educate those around them. They show energy, determination, and industry. The school has shown the people how they can raise a bale of cotton to the acre instead of a third of a bale, the average yield for the county by intensive farming and by using the cotton seed as a fertilizer, and how they can get 25 bushels of corn to the acre instead of 15. Manual training has been developed out of the repair shop. (164, 167-169.)

Mr. Dillingham says there is at Calhoun a neighborhood of farms and homes grouped about a civilizing center, with a school, church, etc., endeavoring to overcome the poverty and isolation of the farmer's life. He looks to the farm village especially to protect the life of children. A short time before the Calhoun School was founded there was a race war in Lowndes County, but now the feeling between the races is pleasant, and white and colored people are working together at Calhoun. A Southern white man sold one of his plantations to the school, and is practically the agent of the school. (165.)

Mr. Dillingham says a farmers' conference is held each month, which is a school in farming for the older people. The economic gospel taught is to raise food and buy land. The black farmers of the farm village are buying some 3,600 acres. (166.)

Other industrial schools in Alabama.—Mr. DILLINGHAM says that besides the Tuskegee Normal and Agricultural Institute there is a manual-labor school at Huntsville, Ala., and the Calhoun School is trying to establish branch schools. (168.)

D. Agricultural instruction for adults.—1. *Farmers' institutes.*—Dr. TRUE testifies that in some States the farmers' institutes are managed by the agricultural college or experiment station; more frequently they are under the direction of the State board or commissioner of agriculture, and in a few States there is a special State officer known as the Superintendent of Farmers' Institutes. There has been a rapid increase in the number of institutes held. Dr. True estimates that they are now regularly held in about 30 States, and that during the year 1898-99 there were some 2,000 institutes, with a total attendance of about 500,000. When the institutes were first organized the farmers liked best to hear the successful farmers who had had experience in their immediate vicinity, but now the demand is more and more for experts who have made a wide study of agricultural problems. The institute workers have thus far been drawn largely from the colleges and experiment stations, but their staffs are getting overworked, and in one or two places at least there is the beginning of a movement to organize a special corps of institute workers. Dr. True thinks there should be in this country men corresponding to what in France are called traveling professors, who could ascertain what the needs of the farmers are, find out what is being done in the experiment station and in the department of agriculture, and disseminate the information at farmers' institutes and other farmers' meetings. In Wisconsin there are now held annually 120 institutes, with an average attendance of more than 50,000. The best addresses are published in the annual institute bulletin, of which 60,000 copies are distributed, a copy being put in every school library in the State. The State makes an appropriation of \$12,000 annually for this work. Massachusetts, Minnesota, Indiana, Michigan, Pennsylvania, Ohio, and New York are also mentioned as States in which the institute movement has been especially successful. (141, 142.)

Vermont.—Mr. SPEAR testifies that Vermont has a good system of farmers' institutes, from 30 to 40 meetings being held in different localities during 3 months of each winter, under the direction of the board of agriculture, and largely under the auspices of the local granges. (404, 405.)

Massachusetts.—Mr. STOCKWELL says the Massachusetts Board of Agriculture secures for institute lecturers the best talent it can obtain, securing practical men from the colleges and experiment stations and the most successful and progressive agriculturists to discuss their specialties. There is no connection between the institutes and the agricultural college, but all the professors are on the list of institute speakers. The State provides one speaker for each institute. The list of institute speakers and their subjects is sent to every agricultural society in the State, and the institute committee or the member of the Board of Agriculture representing the society selects the speaker and subject best suited to their needs. One or two ladies are among the lecturers, and improved household conditions are discussed, as well as agriculture proper. The people usually meet in the morning and have some topic discussed by local agriculturists, or, if they please, they may select a local lecturer and pay him. The speaker sent by the Board of Agriculture follows in the afternoon; the rest of the programme is made up by the society. This induces a local interest which results in a large attendance. The average attendance in the winter of 1899-1900 was 91, in spite of storms and other drawbacks. Never before had there been such a demand for lecturers.

Mr. Stockwell explains that each of the 34 agricultural societies, in order to receive the \$600 bounty from the State, is obliged to hold 3 farmers' institutes. Where there is no agricultural society, lectures are furnished to granges or farmers' clubs, so that every section of the State is supplied, though the call is greater than can be supplied under the present appropriation. On an average there are at least 8 institutes to a county each year. (893, 895.)

Pennsylvania.—Mr. HAMILTON testifies that the Deputy Secretary of Agriculture organizes farmers' institutes in the various counties of Pennsylvania, providing lecturers on the latest and most improved methods of scientific agriculture. The State makes an annual appropriation for the payment of the expenses of speakers, the rent of halls, etc. The Deputy Secretary has a committee in each county, which meets in June to select the places and dates at which they desire to have institutes held the following season. The State is divided into 5 districts, in each of which the State provides 3 lecturers who are expected to be present at every institute held in their section. The chairman of this board of representatives is an intelligent practical farmer of experience, energy, and judgment, well informed on agricultural topics, and able to express himself clearly. The second man is a scientist, supplied of late years by the State college. The third man is selected because he has succeeded in some special line of agriculture, and is changed from time to time for men who are experts in other lines. The first 2 men are kept throughout the entire season. A pamphlet is published giving the names of the State lecturers, the topics they discuss, and short biographies, so that the local managers can see what line of work each individual is capable of treating, and can select one of the topics put down under the lecturer's name. Local committees are authorized to select persons in the neighborhood who have succeeded in some line of agriculture to lecture or read papers. Institutes generally continue for 2 days, beginning in the afternoon of one day and ending in the evening of the second day. The evening session of the first day is devoted to the interests of the education of farmers and their children, and to it are invited the county superintendent, school-teachers, and school children. Another prescribed session is a woman's session, devoted to the interests of country homes, the care of children, the cooking of food, the science of nutrition, decoration, heating, lighting, and ventilation of country homes, flower gardening, etc. The local managers choose what they desire to have discussed at the other sessions. After each lecture there is an opportunity given for asking questions, which is regarded as the most important feature of the work. Institutes are held in Horticultural Hall, Philadelphia, among the best florists, and the institute workers are expected to stand criticism from the best men in the country. The work is of high grade, and the interest has been very great. The difficulty is to secure halls of sufficient size. As a rule the available buildings are entirely inadequate to hold the audiences. Country churches and sometimes country schoolhouses are used. In 1898-99 about 60,000 farming people were reached in the institute work. (347-349.)

Mr. Hamilton testifies that the farmers' institutes have discouraged the discussion of controverted questions, such as the tariff and the money question, leaving them to orators sent out by the political parties. These questions are thought to distract attention from the real object of the institute work, which is to give information upon practical subjects. (374.)

Ohio.—Mr. MILLER testifies that farmers' institute work was begun in Ohio in 1880 the State Board of Agriculture making an allowance of \$1,000 to cover expenses. After 2 or 3 years the appropriation was gradually increased, and the general assembly came to the aid of the board, so that it was possible to devote from \$3,000 to \$5,000 to institute work. In 1890 a general law was passed, providing for a per capita allowance of 5 mills from the various counties, 3 mills to be used for local expenses of the farmers' institutes held in the county, and 2 mills to be available by the State board of agriculture for its share of the expenses in furnishing speakers, etc. In 1896 the law was amended, making the per capita allowance from the county funds 6 mills, with a maximum of \$250, so that the State board now receives from \$60 to \$250 a year from each county, or about \$8,300 in all, and the local societies receive an equal amount for expenditure at home.

From 1 to 4 institutes are held annually in each county.

Local farmers' institute societies organize under the laws of Ohio by petitioning the State Board of Agriculture, and receiving authority from it. The local societies have a free hand in the conduct of the institutes, under certain regulations adopted by the board. Partisan and religious questions must not be discussed, but the work must be confined to the farm and its interest. Many of the best papers are by women. The employment of woman speakers by the local societies is encouraged; the State board has not yet seen its way clear to employ them. The State board furnishes 2 speakers to each institute, and the speakers travel in pairs, but no two of them work

together more than a week. In some other States the whole work is done from the institute bureau, from 4 to 7 speakers being sent out and conducting the meetings from beginning to end. Some States have 1 or 2 women who lecture on domestic science, etc. There is an average of 38 speakers on the Ohio list, each having from 5 to 15 topics he can discuss intelligently. Each institute consists of 5 sessions, continuing 2 days and 1 evening, and each speaker is usually on for 5 lectures. There is also a State institute at the capital, just previous to the annual meeting of the board of agriculture in the middle of January, at which addresses are delivered by the best men available in the Union, as well as by members of the Ohio corps of lecturers. The interest in the institute work is growing remarkably. The board has applications for several times the number of institutes that it can grant, and many independent meetings are held under the rules of the board. The work is increasingly valuable. Farmers are being encouraged and their work systematized. The average attendance is about 400.

A committee selects the best papers obtainable from the local speakers, with some from the employed speakers, and publishes annually a full institute report, largely made up of the lectures delivered. Of this report 10,000 copies are published for distribution from the Department of Agriculture. It also goes into the general year-book of the department, of which 24,000 copies are printed, of which 19,000 are allotted to members of the general assembly, and 5,000, besides those not used by representatives from the larger cities, are distributed by the department of agriculture. Mr. Miller has asked the committee of the assembly to give the department 25,000 copies, reducing the number available for members of the assembly.

Most of the lecturers are farmers. There are also 5 professors from the agricultural college of the Ohio State University and 5 from the staff of the Ohio Experiment Station. The speakers are selected with a view to their capacity for educating and bringing out valuable discussions among farmers themselves. Mr. Miller emphasizes the importance of the latter feature, and says the very best information and thought has been found in localities which have felt the great need of farmers' institutes. (605-607.)

Minnesota.—Mr. M. F. GREELEY, editor of the *Dakota Farmer*, testifies that Minnesota is the leading State in the Union for farmers' institutes, showing much the largest audiences and a correspondingly advanced condition of agriculture. Frequently the largest hall or opera house will not seat the audience. The average attendance last winter was about 557. Minnesota employs the best and most practical speakers to be found. It seems to be very difficult to get clear-cut speakers on subjects the farmers are interested in who have a practical knowledge of what they talk about. Mr. Greeley says that in communities where institutes have been held there are better stock, better tilled fields, better handling of crops, more contented farmers, and more boys and girls who are satisfied with, and proud of, their independent farm life than across the line in another State where they have not been held. (929, 931.)

North Dakota.—Mr. PROM says the greatest benefit the farmers of North Dakota derive from the agricultural college is through the professors' tours through the State holding institutes during the winter, when the farmers are not too busy to attend and get the best results of the experiments at the college. In December, 1900, 3 professors from the college held an institute in Milton and lectured on the handling of the soil, giving the results of their experiments in the growing of wheat in different ways on different plots of ground, fertilized and unfertilized. The first institute at Milton was held the year before, a very dry year, and the farmers went to get the benefit of instruction from the professors, who had raised a crop during the dry year while the others did not. The institutes are made as attractive as possible, and they are very well attended. (790.)

Mr. PROM says questions concerning elevator service or the grading of grain are not discussed at the farmers' institutes of North Dakota. They are discussed among the farmers only in private conversation, and the farmers have taken no political action to protect themselves. (800.)

Mr. BUDGE testifies that the farmers' institutes of North Dakota are well patronized and the results are good. The president of the agricultural college and 1 or 2 of the professors generally go out to them. The president of the Great Northern Railroad goes to a good many of the meetings. Stock raising and general farming are discussed. (848, 849.)

Maryland.—Mr. AGER testifies that through the efforts of members of the Grange and of the Maryland Agricultural College an appropriation of \$4,000 has been secured for farmers' institutes in Maryland. The Director of Farmers' Institutes secures speakers and gives notice of the meetings and of the subject to be discussed, choosing the

subjects according to the principal agricultural interest of the locality. At the close of the address anyone is at liberty to ask questions. The funds have not been sufficient to permit the sessions to be held longer than 1 day at a time. Mr. Ager thinks the institutes have had a very beneficial effect, but the farmers who need instruction most do not attend the meetings. The attendance, however, is better than formerly. (110, 114.)

Kentucky.—Mr. NALL testifies that attempts have been made heretofore to hold farmers' institutes in Kentucky by appointment of dates, and when the lecturers went to the designated place they would find no one there, or perhaps 2 or 3 or a dozen people. Mr. Nall has had a good attendance at the institutes he has held, because he has had the local backing of a club to work up interest. His plan is to have the local club make local arrangements, appoint a time, and arrange a local programme. He has almost determined not to go among the farmers until they are organized to hold institutes. The professors of the Agricultural College go with Mr. Nall, the State Department of Agriculture paying the expenses. Mr. Nall takes down the gist of what is said, catching all the arguments pro and con on each subject, writes them up, and publishes them in a supplement to an agricultural paper. The supplement is printed by the public printer and sent out to the Kentucky circulation of the paper under an arrangement with the publishers. The Commissioner of Agriculture also buys about 2,000 extra copies of the paper to be sent gratis with the supplement to persons in the sections where few papers are taken. In this way what is said is in the hands of the farmers within 10 days or 2 weeks. Mr. Nall finds that this plan works well, and is stirring up a great deal of interest. He believes it the most successful way of getting the farmers to read and study on these subjects. (812.)

North and South Carolina.—Mr. WHITE says farmers' institutes are held in various parts of North Carolina under the auspices of the State Department of Agriculture, but they are for the whites, and the colored man is not expected to attend. (425.)

Mr. HAMMOND says that farmers' institutes in South Carolina are conducted by a single lecturer, sent out on application by Clemson College. They usually last only 1 or 2 days. One was held in Mr. Hammond's neighborhood and aroused much interest. (828, 829.)

Georgia.—Mr. REDDING says the State of Georgia does not recognize the necessity of farmers' institutes. They have been held in an irregular way, but there are no funds to pay the expenses of managers and speakers. Nothing is being done to improve the condition of the farmer except by organized institutions, such as the experiment station, and to some extent by institutions like the State Agricultural Society. (447.)

Alabama.—Dr. STUBBS says farmers' institutes or agricultural meetings have been held in all parts of Alabama. (769.)

Mr. POOLE, as Commissioner of Agriculture of Alabama, directs the holding of farmers' institutes, being assisted by the professors from Auburn. Mr. Poole's intention is to invite progressive farmers, also, to go with him. (920, 921.)

Louisiana.—Dr. STUBBS testifies that the Louisiana State Board of Agriculture and Immigration organized farmers' institutes some years ago, and they are now held in 50 of the 59 parishes of the State. The farmers meet and discuss agricultural questions under the guidance of a director, who is usually either the Commissioner of Agriculture or Dr. Stubbs himself, or one of their associates, and who takes to them all the information he can relating to the subjects nearest to the farmers of that immediate vicinity. At every institute an attempt is made to select two or three local men to take part. (782, 783.)

Need of farmers' institutes in the South.—Mr. HALE suggests that the agricultural college funds could be used to better advantage in the Southern States in the support of farmers' institutes. (386.)

One great need of the farmers of Georgia, according to Mr. STEVENS, is for the formation of a farmers' institute or club in every county in which the best methods of agriculture, the best machines for labor saving, and other industries of the farmer might be discussed. Industrial education is as necessary to the farmer as to the mechanic, and the farmer can not afford to be behind the age any more than any other man. (918.)

2. Traveling schools.—Dr. TRUE says that besides the ordinary farmers' institutes, men from the agricultural colleges and experiment stations sometimes take up a particular line of instruction in a special locality in such a way that those in attendance get a more systematic survey of the subject than at the ordinary institute. Only a beginning has been made in this work in this country, but it has been attempted abroad to a considerable extent. In England a number of traveling dairy schools are in operation each season. (142.)

3. Reading courses for farmers.—Dr. TRUE speaks of the attempt of Pennsylvania

and some other States to organize regular courses of home reading for farmers. The Pennsylvania State College, which was the first to do this in any thorough way, has enrolled (1899) between 400 and 500 persons who are pursuing these reading courses. A syllabus of the course is sent to each of these students; certain books are recommended, and questions are asked. The answers to the questions in many instances show a surprising degree of proficiency. The work is growing rapidly and taxes the resources of the college. (142.)

4. The agricultural press.—Dr. HOWARD says that the agricultural press has done a great deal of good in connection with injurious insects. Some of the papers have started entomological investigations by soliciting information on certain subjects. The press is also anxious to get hold of results, and disseminates them very rapidly. Many agricultural newspapers are sent to the working officials of the Department of Agriculture without charge. The Division of Entomology receives 75 or 80 every week, from which items bearing upon the work of the division are clipped. (763.)

E. Experiment stations.—**1. History and statistics.**—Dr. TRUE says that experimenting in agriculture began in a regular way in this country with the establishment of agricultural colleges. The first regularly organized experiment station was started in Connecticut nearly 25 years ago. Soon after, stations were organized in California and other States, until in 1887 there were 17 experiment stations in 14 different States. In that year Congress passed the Hatch Act, giving to each State and Territory \$15,000 a year for the maintenance of an experiment station, which must be in connection with a land-grant college, except where stations were already organized. The pioneer stations were largely occupied in organizing the control of commercial fertilizers and demonstrating the necessity of basing their purchase on the manufacturers' guaranty of their chemical composition; but they also made sufficient scientific investigations to indicate that with broadened resources they might render much more service. The organization of new stations under the Hatch Act was therefore taken up with enthusiasm, and stations were soon in operation in every State and Territory. It was easy to find in the faculties of the agricultural colleges men competent to undertake agricultural investigations, and the equipment of the colleges could also be used. The lines of work had already been marked out to a considerable extent by the older stations, by some institutions in Europe, and by the United States Department of Agriculture, the scientific divisions of which already constituted a great experiment station. It was therefore possible for the new stations almost immediately to undertake useful investigations and begin the publication of information. In 10 years more than \$10,000,000 have been expended in the maintenance of experiment stations, of which about \$7,000,000 came from the Federal Government. The total expenditure is calculated to be \$1 for every \$3,000 worth of agricultural products. During the same period the stations have published 3,000 bulletins, exclusive of press bulletins, and 500 annual reports. Their bulletins are sent regularly to more than 500,000 farmers, and about 5,000,000 copies are annually distributed. Separate stations are supported in some of the States, so that the total number of stations in the United States, not counting branch stations, is 54, of which 52 receive appropriations under the Hatch Act. The total income of these stations for the fiscal year 1898 was a little more than \$1,200,000, of which \$720,000 was from the National Treasury. Small revenues are derived from the farms. Sales of farm products by the stations in 1898 amounted to \$65,356.25. The Office of Experiment Stations also had an appropriation of \$35,000 for its work, including \$5,000 for an investigation in Alaska. Experiment station work has been begun in Alaska under the direct supervision of the Department of Agriculture. There is also a very successful experiment station in the Hawaiian Islands, under private auspices, but under the direction of a man formerly connected with the Department of Agriculture and with the Louisiana Experiment Station. (146, 147.)

Dr. True says the experiment stations employed in 1898 in the work of administration and inquiry 669 persons, including 75 directors, 148 chemists, 71 agriculturists, 10 experts in animal husbandry, 77 horticulturists, 29 farm foremen, 21 dairymen, 50 botanists, 46 etymologists, 26 veterinarians, 20 meteorologists, 11 biologists, 11 physicists, 6 geologists, 19 mycologists and bacteriologists, 7 irrigation engineers, 15 in charge of substations, 23 secretaries and treasurers, 10 librarians, and 46 clerks. During 1898 the stations published 406 annual reports and bulletins, besides press bulletins, which were widely reproduced. The mailing lists of the stations aggregated half a million names. There is a steady increase in the correspondence with farmers and in the number of calls upon station officers for public addresses at institute meetings and other meetings of farmers. The station officers contribute many articles to agricultural and scientific journals, and have written a number of books on agricultural subjects. (148.)

2. Character of work.—Dr. TRUE classifies the work of experiment stations under

CLXXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

four heads: (a) Police duties connected with the control of fertilizers, dairy products, etc.; (b) study of the natural conditions and resources of the States; (c) demonstration experiments showing how the results of science can be adapted to local conditions; (d) scientific investigations to discover new truths and new applications of old principles. The experiment stations conduct a wide range of scientific research in the laboratory, the plant house, the field, the orchard, the stable, and the dairy. Dr. True mentions the following subjects as among those to which several stations have devoted attention: Soil investigations; drainage, seepage, and irrigation; fertilizers; methods of cultivation, varieties, etc., of the more important crops; feeding stuffs; dairying; chemical and botanical work; horticulture; forestry; injurious insects; animal diseases; bee culture; poultry culture. (146, 147.)

Protection against fraud.—Dr. TRUE says the experiment stations, especially in the East, have been engaged in the investigation and inspection of commercial fertilizers, and have largely prevented the sale of fraudulent goods. In the State of New York alone over 900 brands of fertilizers were examined in 1898. The stations have also done much to expose extravagant claims made for fertilizers and to show the advantage of home-made fertilizers. The stations have also inspected adulterated foods, especially dairy products, butter increasers and preservatives, concentrated feeding stuffs, quack medicines for stock—especially hog cholera remedies—and have exposed frauds in creamery construction and equipment and in dairy apparatus. (148.)

Removal of obstacles to agricultural industries.—Dr. TRUE speaks of the important work of the experiment stations in investigating injurious insects and plant diseases, and says that the Wisconsin station, by discovering an effective curd test, has provided an effective means of detecting tainted or defective milk at cheese factories, which had caused a loss of from \$100,000 to \$200,000 each summer in that State alone. (148, 149.)

Dr. SALMON testifies that the principal experiment stations have permanent veterinarians and staffs of investigators. He thinks the disposition to investigate the diseases of animals is constantly increasing. (753.)

Influence upon legislation.—Dr. TRUE says:

"The agricultural colleges and stations have been largely instrumental in securing State laws for the inspection of fertilizers, nursery stock, dairy products, falsified foods, and feeding stuffs, creamery glassware, Paris green, and for the suppression of plant diseases and injurious insects. They have also aided in the passage of laws establishing farmers' institutes, fixing a milk standard, organizing associations for the promotion of agriculture, quarantining animals for contagious diseases, sale of oleomargarine, the apportionment and measurement of water for irrigation, State aid for highway improvement, etc." (148.)

Development of existing methods, crops, and industries.—Dr. TRUE gives a number of instances in which experiment stations have aided in the development of existing methods, crops, or industries in the various States. The Louisiana Experiment Station, by developing new methods of sugar making, has reduced or removed previous losses, and has helped the sugar industry also by improving the cultivation of sugar cane. In Connecticut the quality of the wrapper-leaf tobacco has been improved. In New York animal industry and dairying have been helped. The Missouri station bulletin on the draft of wagons with broad tires was thought so highly of by the League of American Wheelmen that a large edition was republished by the league. In Connecticut the Storrs station has studied the nutritive value of forage crops, and conducted cooperative experiments with fertilizers and with nitrogenous feeding stuffs. The Ohio station seems to have shown that more stock food per acre can be secured in Ohio from corn than from sugar beets, and has shown the superiority of shallow over deep cultivation of corn in Ohio. The Mississippi station has done an important work for the South in developing the growth of forage plants and the live-stock industries, together with a demonstration of the value of cotton seed and its products for stock. In Utah the methods of tillage have been improved with reference to the conservation of moisture, and studies of alfalfa have been made. The Nebraska station has promoted the growing of alfalfa and winter wheat instead of spring wheat, so that the State has become a large wheat producer, and its investigations of subsoil have resulted in increasing the yield of corn in some cases 10 to 30 bushels an acre. In Vermont there have been investigations of sap flow, as related to the maple-sugar industry. In California seeds and plants of improved varieties have been distributed, and the wine and olive industries have been helped. In Oklahoma effective investigations have been made in the culture of Kafir corn. In Rhode Island there have been important investigations in the feeding and breeding of ducks and geese. In Arkansas there have been experiments on economical methods of producing beef in connection with the raising of cotton. (149, 150.)

Introduction of new methods, crops, and industries.—Dr. TRUE says:

"The Wisconsin station has been instrumental in introducing a variety of barley known as the Mansbury barley. This increased the average yield several bushels per acre in Wisconsin with a

result worth millions of dollars annually to the State alone. This station and the Minnesota station have been largely instrumental in introducing the growing of rape in these States, and it is now grown on thousands of farms to the advantage of the farmer. The Wisconsin station was fortunate enough, after several other stations had made imperfect successes, to perfect a reliable milk tester—the Babcock milk tester—and that has very largely revolutionized the business of dairying in this country."

The Pennsylvania station and many other stations have investigated sugar beets. Their work, in connection with that of the Department of Agriculture, has shown definitely where good sugar beets can be grown. The Maine station has shown that apples can be raised in Aroostook County. The Storrs station, in Connecticut, has made important investigations in nutrition. The Ohio station has originated a method of watering greenhouses by subirrigation. In Florida the introduction of the velvet bean has resulted in the saving of thousands of dollars on fertilizers. Cassava is another new crop, from which starch can be made cheaply. The California station has been engaged in soil investigations, especially on alkali lands, resulting in bringing into agricultural use large tracts of land which were thought to be useless. Kafir corn was introduced into Kansas by the Department of Agriculture, and taken up by the Kansas station. In 1898 over half a million acres of this corn, valued at \$6,000,000, were grown in Kansas. It is a dry-soil plant, which is a great advantage for certain regions. (150.)

3. *Work of certain stations.*—*Massachusetts.*—Mr. STOCKWELL says the Massachusetts Experiment Station could not take up all the lines of experiments called for when it was started, but chose those which seemed most pressing, and has obtained exceedingly good results. Before the establishment of the experiment stations experiments by private individuals were often widely advertised as demonstrating some particular truth, but were afterwards found to be the results of 3 or 4 years of continued peculiar conditions. The experiment stations take no chances, but make such conditions that the result of the experiment is assured. The Massachusetts station is at work testing fertilizers and seeds, the relative value and productiveness of grasses and forage crops, insecticides, and remedies for diseases of trees and plants, the sterilizing of soils to promote plant growth, stock feeding, and the relative value and productiveness of grasses, fruits, and vegetables for market. All the experiment stations in New England are doing a very great deal for agriculture. (894.)

Mr. Stockwell testifies that the agricultural college and experiment station are separate organizations, but work in harmony. (895.)

New Jersey.—Mr. COLLS testifies that the agricultural college and experiment station have been of great benefit to the farming community of New Jersey as a whole, though perhaps half the farmers do not realize it. The experiment station has forced manufacturers of commercial fertilizers to give a better grade of fertilizers for the money. A farmer can send a sample of a fertilizer to the station and have it analyzed. (126, 127, 130.)

Ohio.—Mr. MILLER says the Ohio Experiment Station conducts experiments as to crop production, fertilizers, and the enemies of agriculture, and has given very much needed information. Fertilizer experiments are made by the application of fertilizers on plots of ground on which various products are growing, and making very careful determinations and deductions. The station is criticised by those who are not given to scientific investigation, but the spirit of cooperation with it is very greatly increasing. There are two branch stations—one in the northwest and one in the northeast of the State—the principal station being in Wayne County, in the central part. The station is not connected with the agricultural college. It has the franking privilege and distributes bulletins. (610.)

Minnesota.—Mr. POWERS says there was originally but 1 experiment station in Minnesota, but subsequently 3 more have been opened, all connected with the college of agriculture. One is located in the northern part of the State to investigate the character of the farming best suited to the northern pine lands, which have a different kind of soil from the south or the Red River Valley. (183.)

Mr. Powers says the agricultural experiment stations which show the possibilities of agriculture in the various States have done most for the farmers. The Minnesota station has been one of these. While the farmers were changing from an almost exclusive cultivation of wheat to a diversified system of agriculture, the experiment station was finding out what system of diversified farming was best suited to each section of the State. Mr. Powers does not think that any of the Eastern States are doing enough practical work in this line. (177.)

North Dakota.—Mr. PROM says there is an experiment station connected with the North Dakota Agricultural College which is doing good work along practical lines. The bulletins can be had by sending for them, and the professors state their results at the farmers' institutes. (791.)

CLXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. BUDGE says the North Dakota Experiment Station makes tests on seeds, stock, soil, fruits, etc. It is of great advantage to the farmer who visits it. (848.)

South Dakota.—Mr. GREELEY testifies that the South Dakota Experiment Station is doing very hard, thorough work, but largely along lines of little practical value to a large part of the State, owing principally to its situation in the southeast corner of the State, in a section of country very much like Minnesota and Iowa, where there is nearly always ample moisture, which nearly two-thirds of the State lack except for certain kinds of stocking and farming. The experiments, also, are similar to those carried on in Iowa and Minnesota, and there is not the best kind of feeling toward the station on the part of the farmers of the central and western parts of the State.

Several years ago Mr. Greeley introduced in the State legislature a measure asking for a substation to be located at Highmore. Afterwards the Government sent a man to the station and allowed it to be under the care of the director of the experiment station at Brookings. The State appropriation in 1901 was \$1,000. This is a drought-resisting forage substation, established to look after the interests of the drier sections of the State. Experiments are conducted for drought-resisting forage plants only—those supposed to grow without irrigation. Mr. Greeley pleads for a more elastic interpretation of the experiment-station law, which would permit part of the fund to go to this substation, which seems to the stockmen of the State the more important of the two. The question how to get drought-resisting forage crops means everything to nearly one-half of the State and very much to nearly all of it. (932.)

Maryland.—Mr. AGER testifies that the Maryland Experiment Station has been a great help to the farmers of the State. In some cases various kinds of crops have been experimented with in different portions of the State. The professors lecture at farmers' institutes and at grange meetings. In 1898 the average yield of wheat in Maryland was not more than 20 bushels an acre, but at the agricultural college they produced 40 bushels an acre. After a warm spell, early in April, it turned cold, and the plants were weakened; but at the agricultural college they used 100 pounds of nitrate of soda per acre, and the professor of agriculture attributed the large yield to that cause. The members of the Maryland Grange mix their own fertilizers according to the formula given by Professor Patterson. Some of the members used soda and phosphate under his direction for early potatoes, leaving some rows without the fertilizer. Where the soda was used there was a good crop, and where it was not used there were hardly any marketable potatoes. The fertilizer made a difference of several hundred dollars to those who used it. (107, 108.)

West Virginia.—Mr. CLOHAN, of West Virginia, says:

"Our experimental station has spent a good deal of its time in what a great many of us thought was foolishness, proving that lettuce could be raised successfully under electric lights, and mushrooms could be grown under certain conditions, and that cucumbers could be made in a hothouse—you could raise them to have them all winter—and a great deal of that which we all think would be a great deal of benefit if we were all retired millionaires and were running our conservatories, but we do not exactly see where it interests the fellow who has bought a farm and only paid \$1,000 on a \$5,000 or \$6,000 farm. We do not see how it is going to help that fellow out."

Mr. Clohan does not think the benefits derived from experiment stations quite equal their cost, but he says the farmers of West Virginia have a far better feeling toward the experiment station than at any previous time. Since farmers' institutes have been introduced, and members of the station staff have come into actual contact with the farmers and found what kind of experiments they wanted conducted, their work is coming to give much better satisfaction. When disease breaks out among plants, or anything goes wrong, these men will come to the farm and conduct their experiments where everyone can see that it is a benefit; but when they are conducted in the laboratory the average farmer can not be made to believe that it is not all tomfoolery. (595, 602, 603.)

Mr. Clohan testifies that the West Virginia Experiment Station makes experiments in the growing of grain by distributing new varieties and sending out fertilizers to be used, suggesting different methods, and having careful experiments made as to the results. He regards this as practicable and beneficial. In both of the panhandles of West Virginia, which are fruit-growing sections, the farmers are being guided a great deal by the experiment station with respect to the codling moth and spraying. (595, 602, 603.)

Kentucky.—Mr. NALL testifies that the Kentucky Experiment Station is under the direction of Professor Scovell, a very competent man, who, by going out to the farmers' institutes and mixing with the farmers, finds out where improvement is needed, and also keeps in touch with the National Department of Agriculture, getting the newer varieties of seeds and plants and testing them, and testing all kinds of fertilizers by having alternate rows with and without fertilizers. The results of

his experiments are sent to the farmers in bulletin form. There are also professors of entomology, agrostology, and geology, who come to the farmers' institutes and find out what the people want. Professor Scovell, by experiments, shows the farmers what is lacking in the soil. Sometimes he shows where there has been a failure in the use of fertilizers, tells them what the trouble is and how to remedy it. (812.)

Georgia.—Mr. REDDING, the director of the Georgia Experiment Station, says the experiment station is for investigation and research primarily, and it attempts to get the farmers to follow the methods found to be best. The great freeze of February, 1899, killed the oats, except as they were planted where the experiment station directed. The farmers are adopting methods by which they can save themselves further destruction by frost. (447.)

Alabama.—Mr. WHITNEY says some important experiments in the culture of soil bacteria have been made at the Alabama Experiment Station at Auburn. (882.)

Louisiana.—Dr. STUBBS says there are 3 experiment stations in Louisiana, one at Audubon Park, New Orleans, one in connection with the Agricultural and Mechanical College at Baton Rouge, and one at Calhoun, in the northern part of the State. There is a noticeable interest in experimental work in Louisiana. The State contributes \$25,000 a year to the stations, besides the amount received from the United States Government—probably a larger appropriation for experimental work than any other State except New York.

When the sugar planters started the station at Audubon Park, it proved of such benefit that when the Hatch bill was passed establishing a station in every State and Territory, the State legislature determined to divide the \$15,000 a year into 3 parts, giving one-third to the sugar experiment station already established by the sugar planters, one-third to the station at Baton Rouge, and the other third to the hill farmers in northern Louisiana, and directed the Board of Agriculture to secure a location for the third station. Bids were invited from the different parishes, and the competition resulted in the parish giving all the lands, buildings, mules, and equipment. The station has become a very valuable ally to the small farmers.

The station in northern Louisiana has become a social factor of great prominence. The agricultural camp meetings and other meetings of the Northern Louisiana Agricultural Society are held there. The station has revolutionized the agriculture among the small farmers of that section. It has introduced new methods, new plants, and new seeds, and the study of experiments in the field has been an object lesson and a revelation, widening the mental horizon of the farmers. Modern dairy methods have been introduced, and the farmers are now competing in the market with first-class butter, though they never sold butter before. The station has a fine dairy, and has different varieties of sheep and hogs; also orchards and gardens and a tobacco barn. The main gain has been to take the farmers' attention away from cotton as the sole money crop. They formerly raised a little corn, but their lives were primitive. Their butter was a white product, but now they make first-class butter. They are as up-to-date as any farmers in any part of the country. They can discuss agricultural topics with great intelligence. (780, 781.)

Dr. Stubbs, director of the Louisiana experiment stations, after having been in the State 16 years, supposes he can shake hands with and be recognized by almost every farmer in the State. (769.)

Sugar experiment station.—Dr. STUBBS says the planters of Louisiana established the sugar experiment station over which he presides 15 or 16 years ago, and have spent over \$100,000 for equipment. They have found it profitable, because they continue to support it. The improvements and better methods that are being adopted in the cultivation of sugar cane are largely due to the experiment station and sugar school. A good many beet-sugar men, also, have been educated there, and are scattered all through the beet-sugar factories of the West. Dr. Stubbs says the experiment station is more practically beneficial to the sugar industry than the school, because it is 6 years before the boy can put his knowledge into practice, while the station's methods are taken hold of by the planter at once and carried into his field or sugar house. (780.)

4. *Distribution of bulletins.*—Dr. HOWARD says that in several States the experiment-station bulletins are published in large editions of 20,000 copies, and very widely distributed under frank. (763.)

5. *Coordination of work.*—Dr. TRUE says the experiment stations are brought into intimate relations with each other and made to constitute organic parts of a national system through the Association of American Agricultural Colleges and Experiment Stations and the Office of Experiment Stations of the United States Department of Agriculture. The association holds annual meetings, at which questions of general policy and management are discussed, and papers on special topics read. Its proceedings are published by the Department of Agriculture. The Office of Experiment Stations examines the work and expenditures of all the stations, publishes popular

CLXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

and technical summaries of their investigations, collects and disseminates information regarding the work of similar institutions throughout the world, suggests lines of inquiry, aids cooperative enterprises, and, in general, aims to assist the stations in developing and strengthening their work. Nearly 1,000,000 copies of its publications are distributed in a year. (148.)

6. Criticism and valuation.—Dr. TRUE says there has been to a considerable extent a failure to understand the real purpose of the experiment stations and disappointment that they have not undertaken more farming operations. The act under which they operate was framed with reference to the needs of institutions where science was to be used for the benefit of agriculture; so that the stations work from the scientific to the practical, and do not carry on farming operations to show what good farming is, after the manner of the model farm. If the stations are to do their best work, the investigators must be allowed to pursue their investigations according to the methods demanded by the work, and must not be hampered by outside duties. Dr. True says, also, that political influence has worked too actively in the organization of the stations. In most of the States the board is appointed by the governor of the State, and the membership can be more or less shifted for political purposes. There have been shifting policies in the management of the institutions, and the officers have been changed too frequently. There has been a lack of proper organization. At times the workers have been too independent of each other; at other times there has been too much meddling on the part of the board of management. The lack of thoroughly trained men has been one difficulty, and there has been a haste for immediate results and the demand for too many kinds of work. (150, 151.)

Dr. True adds, however, that the experiment stations have every year a better equipment and better trained men; they divide their work more thoroughly among specialists and introduce new lines of work. There is being made a clearer distinction between the educational work which the college can properly do and the experimental work which the station ought to do. Finally, the stations have in an increased measure the cordial support of Congress, State legislatures, and the people. (151.)

"The American experiment station," Dr. True says, "is the most complete and comprehensive system of agricultural research which the world has ever known. Its publications reach farther and come home more closely to great masses of our farmers than is the case in any other country. If any farmer in the United States is not acquainted with the latest information which agricultural science has to give him regarding the means for improving his art, it is because he has neglected to avail himself of the public agencies created for his benefit." (148.)

F. General education as affecting agriculture.—1. **Inadequate public school facilities in rural districts.**—Dr. CROWELL, formerly president of Trinity College, North Carolina, declares that the agricultural people are the most poorly educated people in the country. In Pennsylvania the rural districts get about half as much per pupil as is paid in Philadelphia. If the educational facilities of the country districts were transferred to Philadelphia, New York, or Boston, the people would move away in a mass, or, if obliged to remain, would abandon the school system. No public-school system could exist in the city if it did not maintain a higher grade of educational facilities than is maintained in the country. (336.)

2. **School facilities and school age in various States.**—*New Hampshire.*—Mr. BACHELDER says that in New Hampshire children are required to attend school from 5 to 14 years of age, and at least 12 weeks in the year. Usually they continue to attend until 16 to 18 years of age. The schoolhouses and instruction are not satisfactory, although there is much improvement going on. The course of study is too short and there is not proper supervision. (43.)

Vermont.—Mr. SPEAR testifies that the school age in Vermont is from 5 to 18 years and that every child in the State who can reach the schools is provided for. The curriculum is not arranged with any particular reference to agriculture or any other business. (404.)

Compulsory education, free text-books and transportation in Massachusetts.—Mr. STOCKWELL says the compulsory age in Massachusetts is from 7 to 14 years and the law is very well enforced by the State board of education and State police. The public-school facilities are generally sufficient, though they are not of the best in some of the hill towns. There are high-school privileges in every town, or if there is no high school in a town transportation is furnished to the nearest high school. (887.)

Mr. Stockwell testifies the State of Massachusetts compels the towns and cities to have 40 weeks of schooling each year. There is no distinction on account of color. Colored pupils are permitted to go to the white schools. The State also compels the towns and cities to provide free text-books for all, including the high schools, as well as to have 40 weeks of schooling each year. A bill before the legislature of

1901 provided that the text-books should become the property of the pupils. Mr. Stockwell favors the bill, saying that the old text-books which he studied are the ones he now refers to.

Massachusetts has an old school fund, the interest of which is distributed to the schools, and a small fund raised by taxation each year. The dog tax is added to the school fund, and in Sutton the fund is augmented by an old parish gift. The funds are distributed as far as may be to the weaker schools and the towns where taxation for schooling is most burdensome. The total for support of schools and buildings is \$13,826,243.41; the local taxation burden is \$13,550,395.78; the whole number of children attending the schools is 474,891; the average membership is 399,423; the average taxation cost of support for each child in the average membership is \$26.06; the average cost of support and buildings for each child in the average membership is \$33.92. Some have felt that the amount distributed to the towns should be increased and have asked for an additional half-mill tax in favor of the country towns, to be distributed on the basis of average attendance. That proposition was carried through the legislature 3 years ago and was vetoed by the governor. The richer towns would under this bill get less than they would contribute. Boston would contribute annually about \$500,000 for the benefit of the State at large; but Boston is constantly drawing to itself not only the money of the State, but the best manhood and womanhood of the State. (891.)

Mr. Stockwell says Massachusetts as a State gives less in proportion for schools than any other State in the Union except New Hampshire, while the towns go beyond their ability. Mr. Stockwell submits statistics showing great inequalities in the taxes raised for school purposes between the different towns of the State. (890.)

Township high schools in Massachusetts and Pennsylvania.—Mr. HAMILTON says Massachusetts has township high schools, and outside of a certain zone the scholars are carried to and from school at the expense of the township. The Pennsylvania law also authorizes the establishment of township high schools, providing that where a 2-year course is established the school shall have \$400 from the State fund; where a 3-year course is provided, \$600, and for a 4-year course, \$800; but the law requires an appropriation to carry it into effect, and this has not yet been secured (January, 1900). There are in Pennsylvania, however, several township high schools which are the result of local enterprise. (352.)

New York.—Mr. NORRIS thinks the public school facilities in New York State are very good and growing better. The qualifications of teachers are becoming more exacting; some of those who taught school several years ago can not get a certificate to-day. (324.)

New Jersey.—Mr. COLES testifies that the educational facilities in New Jersey are good. There are excellent public schools and free text-books. (124.)

Mr. DYE says the age of allowable school attendance in New Jersey is from 5 to 18, and of compulsory attendance from 7 to 12 or 16, for 20 weeks in the year. The school facilities are fairly satisfactory, although not sufficient attention is given to the principles of agriculture and to nature study and other practical branches. Compulsory attendance is not vigorously enforced in some localities. (87, 88.)

Ohio.—Mr. BRIGHAM says the public schools of Ohio, even in the country districts, are very satisfactory. The buildings are good and the teaching of a high grade. Few children fail to attend. Up to the age of from 12 to 14 the boys usually attend fully 6 months in the year. After that they may be taken out during the summer months to work on the farm, but will continue during the winter until 16 or 18, and thereafter may go to some higher school. (11, 12.)

Illinois.—Mr. WILSON testifies that the school facilities of Illinois are good compared with other States, but not good compared with what they ought to be. The school age is from 6 to 21. In his own county 80 per cent of the children of school age are enrolled; he presumes this is above the average, as it is a rural county, without cities. The schoolhouses are better than they were 10 years ago. The examinations for teachers Mr. Wilson does not think as severe as they should be in most of the schools. Illinois has a compulsory educational law. Probably 80 or 90 per cent of the children in the agricultural districts receive only a common country school education. Some go to State institutions. There are a few township schools in the State which, he understands, work very satisfactorily, but the system is not general. (246, 247.)

Free text-books in Minnesota.—Mr. POWERS says Minnesota has a free text-book law, the application of which is left optional with the various districts, and has been adopted in a little more than half the State. By its adoption there has been a material advance in the average attendance. Minnesota has a compulsory education law, but the compulsory feature is not enforced. (180, 182.)

North Dakota.—Mr. FROM, of North Dakota, says the school facilities of that State

are very good and the schools well attended, but there are not many children of school age, because the State is populated by young married people. A gray-haired man is seldom seen. (790.)

Mr. BUDGE testifies that the public schools of North Dakota compare favorably with those of any State in the Union, and are being improved as fast as possible. The condition of the schoolhouses is good. The superintendent of public instruction is elected by the people. (847.)

The West generally.—Mr. GREELEY, of South Dakota, says that with the State institutions, church institutions, and ordinary public schools there are really more schools than are needed in many sections of the West. (930.)

Maryland.—Mr. AGER says the school age of children in Maryland is from 6 years to about 20. He considers the school facilities for white children sufficient, but says there is a lack of schools for colored children. The condition of the schoolhouses for both white and colored children is generally good, and there are very good teachers, many of them graduates of normal schools. Free text-books are furnished by the State under a recent law. (106, 107.)

West Virginia.—Mr. CLOHAN, of Martinsburg, W. Va., says there has been an improvement in school accommodations in the last 15 or 20 years, and the length of the school term has perhaps been increased 1 month in his county. The schools are open from 6 to 8 months for all between the ages of 6 and 21. (592, 593.)

Kentucky.—Mr. NALL says nearly every county in Kentucky has one or more graded schools, including the high-school course. Kentucky has a free-school system supported by taxation. It has not a free-schoolbook system, but each county, through the county judge, may expend \$200 annually for books for indigent children. The school trustees in Kentucky are required to ascertain the number in each family from 6 to 20 years of age. About 80 per cent of the children are enrolled in the schools. The Kentucky schoolhouses are in fairly good condition, and improving. He thinks the teachers are as well qualified as in other States. High schools are found only in the cities, towns, and larger villages, and pupils who do not reside in the cities or towns must pay tuition. (813, 814.)

North Carolina.—Mr. GRAHAM, of North Carolina, says the public-school system of that State has existed since 1840. He quotes the State superintendent of public instruction as saying that the rate of taxation on property for educational purposes in 1860 was greater in North Carolina than in Massachusetts. In North Carolina it is the duty of the committee in each school district to take a school census every year, so the number of children of each race of school age (6 to 21 years) is known, and the tax is divided between the two races according to numbers. The educational board makes special appropriations for the small districts, and the schools are kept open the same time in every district, without regard to the number of pupils. The poorer farmers can not spare their children 8 or 9 months; from the age of 8 they work on the farms. Another difficulty is the price of schoolbooks. Sunday schools get for 8 cents what in the public schools costs \$1.50. Mr. Graham says the State should contract for the text-books and furnish them either free or at cost. Whether it is advisable for the State to publish its own books, as California and a few other States do, is a question of economy. The schools in North Carolina begin in December and run through the winter from less than 3 to over 4 months. Mr. Graham suggests that there should be a term in the summer time; there are 6 weeks after the crops are laid by in July when the children could go to school. There is no distinction between white and colored teachers in the matter of wages. (438, 439.)

Mr. WHITE testifies that the school facilities of North Carolina are poor; there is an insufficiency of funds, and the average school term in the State is about 62 days a year. A good many cities have graded schools open from 6 to 9 months in the year. An extra fund being raised by special tax, but in a great many rural districts the schools run perhaps only 30 or 40 days in the year. There are a great many parochial and other private schools in the cities and towns; a great many people, both white and colored, do not care to have their children mix with the children who go to the public school. In the rural districts, in some cases, the school is run as a subscription school for a month or two after the regular term, in the same building and with the same teacher. There was a statute making it discretionary with each school district to levy an extra tax to run the school a longer term, but very few took advantage of it. Even with the short school term, it is a rare thing to find a young man or young woman of 20 years of age who can not read and write and cipher. (424-427.)

South Carolina.—Mr. HAMMOND says that in South Carolina the school fund is raised by a State tax of 3 mills on property and by a \$1 poll tax. The poll tax is expended in the district in which it is raised, and the 3-mill tax is divided in the county. Each school district is allowed to levy a maximum tax of 4 per cent on property for the schools. The State guarantees \$3 for each pupil enrolled in case

the school taxes do not produce so much. The State fund is apportioned among the districts according to the enrollment. The school districts may by law contain not less than 9 and not more than 40 square miles. The schoolhouses are generally very poor. An ordinary white schoolhouse is a weatherboarded building without ceilings, costing with seats and desks about \$200. The negro schoolhouses are about one-third as large. The teachers are not at all well qualified. There are competitive examinations; but the county trustees are indifferent, and the county superintendents are absolutely inefficient. The county superintendents are paid only \$400 or \$500 a year, and are generally political characters without any culture whatever. There is no compulsory education law in the State. The State does not provide books, but regulates their prices, and provides that they shall not be changed oftener than once in 5 years. (824-826.)

Mr. HAMMOND thinks that less per capita is spent upon education in South Carolina than was spent when the schools were voluntarily supported. The parents think the State must do everything and they need do nothing. The only expense put upon them is the purchase of books, and they complain at that. (825.)

Georgia.—Mr. REDDING testifies that the school facilities in the rural districts of Georgia are not as good as 30 or 40 years ago, though they have improved somewhat of late. The teachers in the public schools are not as good as in the private schools. The schools are open 5 months in the year. In the cities and towns they are open 9 months. (451.)

Mr. NUNNALLY says a school term of 5 months is provided and paid for by the State of Georgia. That covers all the time that can be taken from the farms. Some progress is being made in the education of the masses. Both races have the same privileges in the common schools. (455.)

Mr. BARRETT says that the appropriations for school purposes in Georgia have nearly doubled during the past 10 years, but there is still complaint that the school term is not long enough. This, however, arises from the inability of the people to pay heavier taxes. The school age is from 6 to 18. In the cities the children usually attend regularly, but in the country districts they do not. Illiteracy among the whites is 16 per cent; among the negroes, 67 per cent. Augusta is the most illiterate city in the United States, and this is attributed to the influence of politics in the public schools. (53.)

Mr. STEVENS says free tuition in the public schools of Georgia is provided for during 5 months of the year in the agricultural districts, and local taxation is levied to support public schools in the towns and cities for another 4 months of the year, making the urban school year 9 months. This applies to the colored schools as well as to the white; no distinction is made. One superintendent has charge of the whole system of white and colored schools. The teachers in the colored schools are colored, and from an educational standpoint are considered to have the same qualifications as the white teachers. One has to come up to a certain standard before he gets a license to teach. He is examined by the county school commissioner, and is given a license when found qualified. The patrons of the colored schools have the right to recommend some person that they desire for a teacher, and if the person recommended can secure a license to teach he is selected. Sixty-six per cent of the children of school age (which runs from 6 to 18) are enrolled in the schools. (913, 914.)

Mr. HALE says the public-school facilities of his section of Georgia for both whites and blacks are very good, considering the amount of money spent upon them, and are steadily improving. He estimates that not more than 60 per cent of the blacks of school age attend school for more than a very short session, if at all, but a much larger proportion of the white children attend. At one time Mr. Hale had a private school on his fruit farm. (385.)

Alabama.—Mr. DILLINGHAM, of Lowndes County, Ala., says he lives in the land of one-room cabins, inhabited by mere crop-mortgaged cotton peasants. The schools are kept in tumble-down log huts, with no desks, blackboards, or maps, by ignorant teachers, and lasts only 3 months a year. (165.)

Mississippi.—Mr. KYLE says that in some of the towns of Mississippi there are now separate school districts which levy a tax to supplement the amount contributed by the State, and run the schools about 9 months in the year. The legislature appropriates \$1,000,000 a year, which will run the schools for 4 or 5 months, at the end of which time the school is closed unless there is a local tax or a contribution made by the citizens. There is no compulsory attendance law. Mr. Kyle thinks the schools are taught in the winter and in the summer, when it is convenient for children from the farms to go to school. (468, 471.)

Louisiana.—Dr. STUBBS says the public-school facilities of Louisiana are increasing

OLXXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

and the schools improving rapidly. The citizens are taxing themselves very heavily for public schools. (778.)

Dr. Stubbs adds that besides the Agricultural and Mechanical College, Louisiana has two industrial schools, one in the extreme north and the other in the extreme south of the State, both entirely supported by the State, and largely attended. The pupils are taught all the industries, besides the sciences leading up to them. There are also normal schools and denominational schools. The Catholics, Methodists, and Baptists all have colleges in Louisiana. (783.)

3. **Common-school curriculum criticized.**—According to Professor DAVENPORT, farmers say that the family life on a farm is so closely identified with the business life that the child learns all the business hardships, and when he goes to school he is given to read the story of the few phenomenally successful men in other than agricultural lines; so the feeling is that they should be better instructed in the normal features of country life. The farmer complains that when he sends his child to school he goes into an artificial world, having absolutely no reference to rural life, and asks that part of the instruction should deal with the affairs of the country and be coordinated with his experience. The demand seems to be for technical instruction in agriculture, which it will be impossible to get for an indefinite time owing to the lack of teachers; but Professor Davenport believes that the demand when analyzed is not so much for agricultural instruction as for a curriculum which would come closer to the life of the student. This has been introduced in a tentative way in the nature-study work of New York. (264, 265.)

Mr. WHITNEY says that very little or no information about crops and plant and animal foods is taught in any of the common schools that he is familiar with, even in agricultural districts. The ambitions of the pupils are led into other pursuits than agriculture. Mr. Whitney thinks that the curriculum could be changed to advantage in some cases. (870.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, considers that the school curriculum is very poorly adapted to the future needs of those who are to make farming their occupation. The ordinary common school teaches reading, writing, arithmetic, geography, and some English grammar, and physiology is now required in Pennsylvania. No instruction is given, as a rule, upon common-sense lines relating to the natural objects surrounding the children. Mr. Hamilton feels that the system of education in the common schools of Pennsylvania tends to send children into the towns and cities. The education given is quite elementary, and any boy or girl desiring to secure a fair education must go into some town, where the education and surroundings effectually educate him away from the country. Mr. Hamilton thinks this accounts for the overpopulation of cities. He suggests as a remedy the teaching of nature topics, as is done in France and Germany, to some extent in Canada, and, within a few years, in New York. (351.)

Mr. MORAN, of Minnesota, complains that farming is scarcely mentioned in the common schools, and that there is nothing in the schoolbooks to encourage a boy, stimulate him, or train his mind to look upon the occupation of farming as being honorable. (709.)

Mr. PROM, of North Dakota, says the course of study in the public schools is, of course, not sufficient for the needs of agriculturists. (790.)

Mr. STOCKWELL, of Massachusetts, says actual hard work does not enter into the school curriculum, so that honest hand labor is something the boy and girl do not know until they are 15, and after that they do not think it wise to take it up; so hard manual labor is falling into disuse, and is replaced by costly athletics, except at the agricultural college, and even there sports must be encouraged or the college will lose its students. (887.)

Mr. GREELEY, Secretary of the Board of Regents of Education of South Dakota, thinks there is too much book learning and too little of the practical in the schools. "The bread and butter part of it is neglected." Too many boys and girls go back to the farm, if they go back at all, full of facts and figures, but with no mental, moral, or physical muscle with which to take hold of the business of life. Just when they are considered perfectly educated they are sometimes almost perfectly helpless. Mr. Greeley thinks it would greatly benefit the girls to know more about housekeeping, cooking, nursing, etc., and the boys to learn how to handle stock and get the most out of the soil. The practical part should be worked in with the other part so that each would make the other more available. (931.)

Dr. STUBBS says the course of study in the common schools of Louisiana is not well adapted to agricultural people. It is the same which prevails almost everywhere in the United States. The public schools are not adapted to the wants of any agricultural community whatever. After a great many speeches before farmers and educational organizations, a great many parishes in the State have been about per-

suaded to amend the public-school curriculum by adding agricultural and natural sciences. Three-fourths of the boys and girls in the public schools in the hill section never get beyond the public schools, and become farmers without having studied any kind of science and without the slightest knowledge of the composition of the soil they are going to work, and with no idea of the nutrition of animals, of plants, or of fertilizers. They are called upon to spend a lifetime working at a profession of which they have not learned a word at school. This, Dr. Stubbs declares, is a great blunder, the greatest monstrosity of the present age. They have been taught history, grammar, and the three R's, but nothing about their future life work. Louisiana is now adopting measures, however, which will give the rural schools a course of nature studies in addition to the other branches. In several parishes this has already been inaugurated. (779.)

Mr. BROWN believes that the lack of prosperity of Southern farmers and Southern people generally is due to the lack of education in practical lines. White boys have been educated with the idea that they would not have to work. In the common schools, high schools, and colleges industrial education and agricultural training should be introduced. (62.)

Mr. DILLINGHAM expresses the fear that the public schools have a tendency to unfit negroes for the struggle for existence, tending to make them think they can go through life without working. (167.)

Mr. WILSON does not regard the common-school curriculum as sufficient for the needs of an agricultural people, but says there is a tendency to improve. He believes that the technical education of agriculturists should be encouraged. (247.)

Mr. POWERS thinks the adaptation of the public-school curriculum to the needs of the agricultural people is improving. (183.)

4. Agricultural education and nature study in common schools.—Mr. BRIGHAM believes that the public schools in country districts should give some instruction in the elementary principles of agriculture, such as the character of soils, the means of maintaining their fertility, the chemistry of farming to some degree, and the proper method of feeding stock. (12.)

Mr. JONES adds that the National Grange is advocating such instruction. (29.)

Besides agricultural schools after the plan of those in Minnesota and Nebraska, of which there should be a number in different parts of a State, Dr. TRUE suggests the introduction of outline courses in the theory and practice of agriculture in the high schools in or near rural communities. The cities are constantly developing their schools in manual and technical training, and the same thing ought to be done for agriculture. Many high schools already have at least 1 teacher, chosen because of his ability to teach natural science. This teacher might just as well be a person who has studied scientific agriculture, and could offer an optional course in agriculture. Dr. True doubts the expediency of teaching agriculture in the larger cities, but thinks it might well be taught in a great many cities which are intimately associated with rural communities. There are cities of 50,000 to 60,000 inhabitants which are really rural centers as well of agricultural population. In a city like Des Moines, for instance, there are probably in the high school quite a large number of students who have come in from the rural schools to finish their education, and in such a school it would be very appropriate to have an optional course in agriculture. (140-144.)

Dr. TRUE says that the teaching of agriculture in elementary schools has been undertaken in some European countries, in some cases with considerable success. He has heard a teacher in a village school in Belgium giving instruction on milk to children 12 and 14 years old, who were much interested. The demand for the introduction of new studies into elementary schools, growing out of the broadening of human knowledge, makes it difficult to determine how far any special subject like agriculture can be wisely introduced. This kind of work requires special training and adaptability on the part of the teacher, and it has been difficult to find teachers who are properly trained. Generally speaking, Dr. True does not believe that the formal teaching of agriculture can be introduced into common schools under present conditions; but nature study can be introduced into the common schools, and in the rural schools the subjects which will naturally be selected will very largely be subjects relating to agriculture. This movement for nature study has begun very successfully in New York, and has spread into other States. This seems to Dr. True to be the coming movement for the improvement of rural schools in a direction to benefit agriculture. The State of New York makes an appropriation of \$35,000 to the College of Agriculture of Cornell University for extension work. A part of the money is to be spent in some experiments in different parts of the State, and a good deal of it is used in the preparation and dissemination of leaflets on nature subjects, which may be used by teachers in preparing simple lessons for use in elementary schools.

CLXXXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

The instructors in the agricultural college attend teachers' institutes and farmers' meetings to explain this movement. This work is so popular that it becomes an embarrassment to those in charge of it. The city schools see in it an opportunity to improve their course of study, and the demand for the leaflets has come to a considerable extent from city teachers. One of the greatest difficulties in such movements grows out of the conservatism of the farming population. (142, 143.)

Mr. STROCKWELL says the knowledge required of the farmer is so general that the common schools can supply only the foundation. No one needs a more technical and thorough knowledge than the farmer. Each farmer has different kinds of soil, and to know what fertilizers and crops will make the best returns requires an education that can have only its foundation in the public schools. (887.)

Mr. AGEH, master of the Maryland State Grange, thinks that nature studies and agriculture should be taught in the schools. He believes it as important that the boy should be taught agriculture as that a young man should be taught any other profession which he intends to follow. Agricultural chemistry should be taught in order that farmers may be able to analyze soils and fertilizers and know their value. The first principles of agriculture should be taught in the primary schools, and wherever possible prospective farmers should go to agricultural colleges and have practical instruction. In dairying it is very important that one should be able to ascertain the amount of butter fat in milk and know how to select a good cow. (107.)

Mr. CLOHAN, of West Virginia, would like to see some branches taken out of the public schools and replaced by something more directly pertaining to agriculture. He thinks botany and agricultural chemistry would be far better for the average farm boy than the languages. He would like to see these subjects taught experimentally and in a way to make them interesting. (594, 595.)

Mr. DILLINGHAM advocates elementary agricultural training in the common schools, such as is given to some extent in Ireland, where schoolhouses have plots of ground in which the children cultivate the staple crops. Russia and Austria, he says, are doing similar work. (167.)

Mr. COLES is of the opinion that the elements of agricultural chemistry should be taught in the public schools. He says Professor Voorhees, of the New Jersey Experiment Station, has published a book which is being introduced into the public schools of that State, and predicts that it will pave the way for more advanced education in that line. (124.)

Mr. NALL, of Kentucky,

"would suggest for rural sections that the system should embrace something that bears upon agriculture, give the children a love for the occupation, make children believe that they are growing up to be farmers, keep them from leaving the farms, and make them realize that they ought to understand more about that subject than their fathers do or grandfathers did." (813.)

Mr. DYE also believes that the public schools should give more training in practical branches relating to agriculture. There should be more nature study and training of the hands and eyes. (88.)

Mr. HANLEY believes that there is too much theoretical and not enough practical knowledge taught to children; in the country there is not enough education of any kind. He believes that in the agricultural districts subjects related to agriculture should be taught, such as the nature of plants and animals. He would give the boys some idea of theoretical farming, and the girls education in sewing, baking, and other useful employments which they will probably be called upon to carry out, instead of the notion that labor is disreputable. (277, 278.)

Dr. CROWELL says the children in every agricultural community should be taught among the first things they learn what the resources of the family and of the community are and how the utilization of the resources of the community can be improved. (336.)

Mr. KETCHUM, who was formerly engaged in farming, is not an enthusiast on the subject of introducing the elements of agriculture into the public schools, for the reason that the majority of the schools, even in the country districts, are located in villages and towns and made up of as many pupils who are not the children of farmers as those who are. (134.)

Nature study.—Mr. HAMILTON thinks the schools ought as rapidly as possible to adopt nature study; that normal schools should begin at once to prepare teachers for giving that sort of instruction, and that reading books used in the public schools ought to have a considerable amount of matter devoted to natural-science objects, so that the children will become familiar with things the agriculturist needs to know. (352.)

Mr. STEVENS, Commissioner of Agriculture of Georgia, says the curriculum of the public schools is not specially adapted to agriculture, but there is a move on foot to require the schools in the rural districts to teach nature studies, including agricul-

ture. The State department of agriculture from time to time has recommended legislation on this subject. There is a school of technology in Atlanta and there are technical schools in Savannah, Macon, Columbus, and Sandersville. (914.)

Mr. GREELEY, secretary of the Board of Regents of Education of South Dakota, says that if nature study is brought into the schools it must come in a practical form, and we must be very careful who is employed to teach it. He does not think it possible to do very much in this line, but hopes something may come of it. (932.)

Nature study in New York, Pennsylvania, and Massachusetts.—Mr. HAMILTON testifies that Cornell University is putting out teachers' nature-study leaflets, prepared by the best natural-science scholars the country has, in simple language. The teacher reads these over and gives talks to the children on the subjects treated, getting them to search for the things mentioned and perhaps write an article upon what they see. In many of the common country schools junior natural-science clubs are being formed among the children, who collect samples of the plants and insects of the neighborhood, write descriptions of them, and send the papers and specimens to Cornell University, where they are examined and the writers graded upon their descriptions. Thus great interest is excited in nature study. Teachers make excursions with the children and call attention to natural objects of interest, and in some instances raise plants in the schoolroom. Pupils make drawings of these plants and write essays upon them instead of on abstract questions. Thus they are taught observation and interested in the wonderful things about them, in the hope that they will stay in the country.

The Pennsylvania State College has also begun the publication of a series of nature-study leaflets to be sent out to the school teachers, who are required to pass an examination on each topic before securing a leaflet on a different subject and also to make some statement as to the use made of it in school. The cities are doing more in the way of teaching nature topics than the country, because the teachers are better paid and of higher grade. (351, 352.)

Mr. STOCKWELL says nature studies are now being introduced in the Massachusetts schools. Nature-study leaflets are being sent out to the schools in such numbers as they desire. Within 2 or 3 years there has been a marked advance in the matter of interesting children in nature studies with good results. (887.)

Teachers' classes in New York.—Dr. TRUE says that the State of New York gives to every high school that organizes a teachers' class with a certain number of students a subsidy, varying according to the number of students. This enables the high school to get a teacher who has had instruction in the normal school to give an outline course in teaching. Dr. True thinks this plan might be applied to the teaching of agriculture in high schools. (141.)

Need of suitable text-books.—Mr. MORAN, of Minnesota, president of the National Grain Growers' Cooperative Association, advocates the compulsory use of a text-book on practical farming. He says the General Government should ask specialists to prepare brief articles on all subjects connected with farming, showing the extent of the industry and the importance of understanding the mysteries of nature and the character of plants. He would have the text-book furnished under the direction of the Department of Agriculture for use in country and village district schools, and also in as many town and city schools and colleges and universities as possible. (708.)

Mr. HALE says the need of the South in the common schools, both black and white, is for simple text-books in the line of agriculture, such as the Rural Science Series. One or a number of these books ought to go into the rural schools of every section, but there is more need of it in the South than elsewhere. Professor Hilgard's work on Leguminous Plants and Nitrogen is particularly important in the South. (385.)

5. *Township high schools advocated.*—Mr. HAMILTON believes the most important thing after the introduction of nature study is the establishment of township graded and high schools in country districts, so that country children could be educated in the country, kept in contact with their home people and home duties, and so protected from town life until they are of sufficient age to understand the relative value of different kinds of life. (352.)

6. *National aid advocated.*—Mr. NUNNALLY, of Georgia, knows of no legislation that would benefit the South more than an appropriation to aid the common-school system. The small pay of the teachers shows that more money is needed. (455.)

7. *Influence of education upon agriculture.*—Professor BAILEY says the only fundamental remedy for poor farming is education, and he thinks that the actual progress in that direction most encouraging. "Many of the questions that farmers discuss to-day were wholly unknown to them a generation ago. Farmers' meetings are well attended, and the discussions are clear-cut, practical, and pointed. Anyone who is familiar with the present attitude of farmers will have no doubt of the future.

CLXXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Present-day farming is full of vim and vitality, and it is constantly improving." (1013.)

Dr. CROWELL, formerly president of Trinity College, North Carolina, says the application of science to agricultural processes is necessary. The farmer will take to technical education in agriculture rightly planned and taught, but technical education run mad, consisting in feeding 70 different kinds of food to 90 different kinds of pigs, he will not take much stock in. (336.)

Mr. POWERS thinks the basis of technical education in agriculture must be among the farmers, and will begin by developing among them a knowledge of better methods of agriculture. (183.)

Mr. REDDING thinks it very desirable for a young man going on a farm to know how to do everything on the farm in an expert manner. (451.)

Mr. WIETING, Commissioner of Agriculture of New York, says that the idea that education unfits a man for farm life is passing away in New York. Many educated young men are devoting their knowledge and energies with pride and satisfaction to agricultural pursuits. Such farmers become business men, keeping books in which the results of their operations are definitely determined. The State of New York is doing what it can to spread the knowledge of scientific agriculture throughout the whole farming community. It is trying to lead the people out of the old ruts into the production of more profitable crops. It hopes to stem the tide toward the city and perhaps turn it back toward the farm. (994.)

G. The application of science to agriculture.—1. **Agricultural education and research in America.**—Dr. TRUE sums up the general results of the movement for agricultural education and research in the United States substantially as follows: (1) A body of trained leaders and experts; (2) an up-to-date American literature on American agriculture; (3) free distribution of a vast amount of accurate and useful information; (4) a breaking down of the tradition that agriculture is of necessity a nonprogressive art; (5) the colleges and stations have been an important factor in making the state of the ignorant, shiftless, and nonprogressive farmer worse than formerly. It is becoming clearer every year that to be successful in agriculture, as in other arts, one must be progressive and seek up-to-date information and ideas. (151, 152.)

Mr. MORAN, president of the National Grain Growers' Cooperative Association, advocates a more generous Government aid to State agricultural colleges and experiment stations. (708.)

2. **The farmer's attitude toward the scientist.**—Dr. HOWARD, Chief Entomologist of the United States Department of Agriculture, says there is a very rapidly growing appreciation by the farmer of science as applied to agriculture. In Dr. Howard's early experience before farmers' conventions he was listened to with indifference; the farmers regarded a man who talked about the application of science to agriculture as a theoretical fellow who had not the necessary practical experience, but the results which have been achieved by the Department of Agriculture have been so great that the farmers have changed their attitude entirely. Now when one of the specialists addresses a farmers' meeting he is listened to with respect, and after he finishes his talk is kept on his feet for another hour to answer questions. The State agricultural experiment station men reported a similar experience. (762.)

3. **Particular uses of scientific agriculture.**—Dr. TRUE thinks that impoverished soil can not be reclaimed or made profitable without the use of scientific agriculture in the broad sense of the term. (145.)

Mr. DYE says that chemical study of the capacities of soils, their proportions of plant food, etc., has been of great advantage in enabling farmers to adjust their crops to the soils, to use fertilizers, and otherwise work their lands properly. (88, 89, 93.)

Professor DAVENPORT testifies that as a result of the invention of the Babcock test, by which the actual butter production of each cow can be ascertained, farmers have often destroyed 25 per cent of their cows and obtained more profit from the remainder than from the whole herd. Those neglecting to cull out their bad cows will be unable to produce in competition with those who do. (260.)

While Mr. HANLEY has not much regard for theoretical farming, he concedes that the work of professional men in checking animal diseases and insect pests is of immense advantage to agriculture. (282.)

4. **Scientific agriculture in New York.**—Mr. FLANDERS, Assistant Commissioner of Agriculture of New York, states that the use of scientific methods of farming is increasing in that State, and he attributes the change to the teaching of the agricultural schools and colleges and to the instruction given at farmers' institutes, of which 300 or 400 are held under the care of the State authorities every year. The attitude of the farmers toward the agricultural college is favorable, and many of the successful farmers of the State are sticking closely to scientific principles. (995, 998.)

VII. DEPRECIATION AND IMPROVEMENT OF SOILS.

A. Exhaustion and maintenance of fertility.—1. The problem stated.—

Professor DAVENPORT says the race has been in the habit of going west upon new lands ever since it started from India, but is now about done going west. The problem in agriculture is now not so much how to produce crops a cent or two a bushel cheaper, as it is how to maintain the fertility of the soil for a few years and what class of men shall control the land. Under a system of farming by an American peasantry, the fertility of the soil would be lost; but with good management agriculturally good land will become more productive. Until recently American farming has meant raising cheap crops without much reference to the effect upon the land; but a farmer can get as much income while improving the soil as he can while letting it deteriorate. (232, 233.)

Professor Davenport adds that there is no way of maintaining indefinitely under agricultural operations all the fertility in extremely fertile lands. After 15 or 20 years, or 30 or 40 years on the very best land, the fertility begins to fail, and the question of fertility must be considered. (269, 270.)

Dr. WILEY says there is no crop which can be grown *ad libitum* on the native fertility of any soil whatever, and any radical system of agriculture—growing beets, cotton, or any other crop—must look to a period when the land must be fed. When the wheat-growing regions of the Northwest were first opened they were able to grow 30 or 40 bushels to the acre; now the yield is 15 bushels on the same fields. A system of agriculture which robs the soil is not just; a man who leaves a farm poorer than he found it has committed a crime against society. Any system of agriculture which impoverishes the soil is a false one; a rational system of agriculture increases the fertility of the soil. The population of the earth is constantly increasing; the area which is subject to culture is practically exhausted; but scientific agriculture will increase the fertility of land. It is far better to grow a less area, and get a larger yield than to impoverish the soil. Scientific agriculture will show how to conserve plant food so as to make it cheap and accessible to every farmer. This has already been largely accomplished, and every agricultural product will feel the effect of properly feeding the soil. A country which merely plows, sows, and sells will become bankrupt sooner or later; that country will remain rich in agriculture which feeds its land. (647, 648.)

2. Exhaustion of soils in certain localities.—New England.—Professor DAVENPORT explains the depreciation in fertility of New England farm lands by saying that the American has never taken kindly to the use of manure, and gives his land hard usage. In the Mohawk Valley the manure used to be dumped into the river to get rid of it. The tendency has been for the typical farmer to retire from poorer land to better land, rather than put more labor on naturally unfertile land. (263.)

Mr. STROCKWELL, of Massachusetts, says too many farmers are mercenary from necessity. The need of the present dollar taxes all their present energies, and the future of the farm must be forgotten because of present necessities. (892.)

New York.—Mr. NORRIS, of Sodus, N. Y., says that when the soil of his section of New York was in its virgin state it produced from 30 to 40 bushels of wheat without any fertilizers, but to-day, with fertilizers and a high state of cultivation, the average yield has decreased to about 25 bushels. While not doubting that the cost of production has been reduced in the West, Mr. Norris says the cost of growing a crop in the older sections has increased, because it is necessary to use artificial fertilizers and keep up a better state of cultivation than when the soil was in the virgin state. The productivity of the soil has diminished one-third, and in many cases more than one-half in New York. No one thinks of using less than a ton of fertilizer to an acre of wheat or barley, and that costs \$25 an acre. When the soil was in its virgin state it produced large crops without any fertilizers whatever. To-day the farmer must use improved methods and machinery, as well as fertilizers. (325, 327, 331.)

Western States.—Dr. CROWELL says the farmers on the rich prairie lands of the West have had the same advantages of soil as the Pennsylvania Dutch, but have exhausted the soil until they have been obliged to rotate crops in order to get a return on their capital. (334.)

Virginia.—Mr. WHITNEY, Chief of the Bureau (formerly Division) of Soils in the Department of Agriculture, attributes the deterioration of the tobacco lands of Virginia primarily to the methods of cultivation, which have not regarded the maintenance of fertility. It is almost universally believed in Maryland and Virginia that tobacco is a very exhausting crop; but in Ohio, Kentucky, Pennsylvania, and Connecticut it is the one crop which is valued as a renovator for the soil. That is due, in Mr. Whitney's opinion, to the care taken of the tobacco lands, which has improved

CLXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

the land in spite of the removal of plant food. The Virginia farmers plant tobacco with little or no fertilizer, give the land a clean cultivation, and leave it exposed for a large part of the year. The result is that the soil is said to be worn out. (875.)

Mr. WEDDERBURN says the impoverishment of the soil in Virginia is the result of most outrageous cultivation: continuous cropping and putting nothing back. Up to a few years before the war, when Peruvian guano was introduced, nothing was known about fertilizers; only stable manure was used. The ground was planted in tobacco until it ceased to grow tobacco, then planted in wheat for 2 or 3 years, and then in corn and oats, until the land was killed. (822.)

Georgia.—Mr. LOVEJOY says there is a great deal of worn-out land in Georgia. (79.)

Decomposition of bare soils in the South.—Mr. GEORGE says one reason why the Southern States are sterile is because the humidity and continual warmth decompose the soil. The cotton and corn cover the land only a part of the year, so that the organic elements of the soil are eliminated by exposure. (223.)

Erosion and terracing.—Mr. KYLE says the people of the South are beginning to learn to protect the soil from washing away by side hill ditches and terracing. (465.)

3. *Abundance of plant food in Eastern and Southern soils.*—Mr. WHITNEY, Chief of the Bureau of Soils in the United States Department of Agriculture, has never seen a case in which the exhaustion of soil was probably due to the actual removal of plant food. He knows of no evidence to show that the New England soils have any less plant food than when they were first cultivated. They have all of the essential ingredients for crop production, but the land of the New England States is generally rough, hilly, and often stony, and the expense of clearing and cultivation is considerable.

Mr. Whitney considers it perfectly safe to say that the condition of the so-called worn-out soils of the South is due to conditions which make the plant food unavailable to the plants. Fertility must be restored to the soil, not necessarily by the addition of plant food, but by bringing about such changes in the physical conditions or the chemical combinations as will encourage the natural weathering of the soil, which makes the plant food available. The soil, to be productive, must render annually a sufficient amount of food material in a form available to the plants. The soil is composed mostly of silicates and aluminates, or difficultly soluble compounds of silica, alumina, potash, soda, and lime, which through atmospheric agencies are rendered more or less soluble and available to plants. A fertile soil is one in which the weathering effects render a sufficient amount of plant food available.

Mr. Whitney calls attention to cases in which soils have been cultivated constantly for hundreds and thousands of years with the same crops. The soils of India, which tradition says have been cultivated for 2,000 years, under primitive methods, without artificial fertilizing, still give fair returns. In Egypt, lands which have been cultivated since history began are as fertile as ever. In Europe there are records of cultivation of soils for 500 years. In England historic experiments have been going on for the past 50 years in growing wheat continuously without fertilization; the yield has fallen to about 12 or 13 bushels to the acre, but for the past 20 years there has been little or no difference in the yield, except slight fluctuations due to seasonal conditions. So far as is known, the soil will produce 12 or 13 bushels to the acre annually for hundreds of years. By the use of fertilizers, however, the yield of adjacent plots has been increased to an average of about 30 bushels to the acre, the production being economically increased by this forcing of the crop. (859, 866.)

Mr. Whitney concludes from the results of the English experiments that on a given soil a certain yield can be maintained for a good many years, or perhaps indefinitely. (874.)

Mr. HALE, of Georgia and Connecticut, while admitting that the soil of the East and part of the South is desolate-looking land, says that below the surface it is rich in the mineral elements needed for plant protection. It is lacking in nitrogenous matter, but by growing leguminous crops all the nitrogen that is needed may be gathered from the air. The cowpea, the Japanese soy bean, and the velvet bean, which is said to be the best of all, are grown in Georgia to a moderate extent, and by plowing under the plants they give wonderful crops. Corn has been grown on the same land for 50 years without any fertilizer except cowpeas sown between the rows of corn. (389.)

Mr. Hale believes that the most of the land in America has mineral elements enough to last for centuries, and that by supplying nitrogen, preferably by taking it from the air, the fertility of much of the so-called worn-out land in the Atlantic coast States can be increased. Rotation of crops will strengthen the land, but even cotton and tobacco, which take a great deal of potash, can be grown continuously on the same land and the fertility of the soil maintained. In the Connecticut Valley, where tobacco has been grown for many years with commercial fertilizers, the land

is more fertile than it was 30 or 40 years ago. Mr. Hale went South with the intention of using many thousands of tons of fertilizers a year, but found that there was fertility enough in the land to grow beautiful trees and fruit, if he only stirred it up so as to bring the particles together to get the chemical action, and it seemed unwise to buy phosphoric acid and potash when there was enough in the land to last a hundred years. (392.)

Mr. Hale says, in brief, that the soil of the South has never been tilled very thoroughly, and there is yet great fertility in much of the subsoil; only the surface is scratched off. Many people have a 1-horse plow and a weak mule, and only 2 or 3 inches of the surface are turned over. The opening up of the soil with modern implement, or subsoiling where necessary, brings out an abundance of plant food. (380.)

4. Depreciation of land due to social conditions and poor management.—Mr. WHITNEY says the reputed exhaustion of the soils in Maryland and Virginia and the Southern States generally is unquestionably due to improper and injudicious methods of cultivation. Other causes contributing to the abandonment or depreciation of these lands have been the cheaper production in the West, with reduced cost of transportation, the development of special industries, such as the production of white burley tobacco in other localities, and the changes in social conditions due to the civil war. In many portions of Maryland it has been found possible to obtain a fair profit, but impossible to make a living from the land and also pay the interest on the mortgages which have been running ever since the war. There are otherwise prosperous communities in southern Maryland where families could be maintained with a fair degree of comfort, except that nearly all the farms are mortgaged. Areas are now being abandoned from that cause throughout Maryland and the South. One of the most important causes of deterioration, Mr. Whitney says, is the method of agriculture which prevails throughout this region. The soils of Maryland are not exhausted, for there is sufficient plant food for innumerable crops; but they have been abused, and are not as productive as they should be. Probably about 40 per cent of the area of St. Mary County, Md., has a certain soil with a heavy subsoil, as valuable in its way and in much the same way as the limestone soil of Pennsylvania; yet it sells for from \$1 to \$3 an acre in forest and about \$10 an acre in cultivation, while the soils of Lancaster County, Pa., sell at from \$125 to \$250 an acre. The same limestone soil and essentially the same climatic conditions extend down through the Shenandoah Valley of Virginia, yet the land sells there at \$10 to \$20 an acre, rarely more than \$40 or \$50 an acre. In a certain area in St. Mary County, Md., there have been several good farms well kept up which grow from 15 to 20 bushels of wheat to the acre. The Pennsylvania farmer grows from 25 to 35 bushels of wheat, and a larger yield of tobacco than the Maryland farmer.

Mr. Whitney thinks that the soils of southern Maryland ought to have a higher value, and that the reason they have not is because of the social conditions and the methods of farming. The Maryland farm is seldom worked by the owner. There is usually an overseer, and frequently a tenant farmer who farms in his own way for a portion of the crop, or occasionally for a money consideration. The crops grown are the ordinary staple crops of general agriculture—corn, wheat, and tobacco. Western competition and low prices make them scarcely profitable. The corn is fed mainly to the work stock; the wheat is sold and sent off the farm in exchange for flour, which is bought at a considerable increase in cost over what it would cost if it could be ground in the neighborhood. The farmer buys his meat, groceries, and frequently vegetables that he should have raised in his garden. There is no comparison between the improvident methods that prevail in some of the Maryland or Virginia communities and the thrifty methods of Lancaster County, Pa., and other Northern communities.

The Lancaster County farmer has on his table an abundance and great variety of food. The chances are that the meat was raised by himself, the vegetables grown in his garden, the preserves made by the family from the product of the garden, and even the sugar produced on the place; and nothing but the tea, coffee, salt, and pepper purchased. As a rule, the families are large. The boys and girls are brought up to work on the farm, and it is rare for any of them to leave it. They commonly settle on a portion of it, or on some neighboring farm. The farms are small and the labor is all done by the owner and his family. The girls are brought up to look after the house, and there is no expense for service. Very few products except tobacco and stock are sold from Lancaster County. Not only is all the corn and hay grown there fed to the stock, but it is often imported, so that more beef and mutton can be produced. The wheat is ground in near-by mills, and most of the products of the farm are either used on the farm or manufactured there into a product that is used in the district. In Lancaster and the other towns there is a ready market for

everything produced in the county, and the supply and demand are so nearly equal that very little is sent out or brought into the county. The result is a happy, contented, and prosperous community, which people seldom think of leaving.

Mr. Whitney concedes that the system which has prevailed so long in the South was satisfactory under the conditions of some years ago, but declares that with the rapid improvement in industrial lines and in transportation facilities the old methods are no longer applicable. It seems to him that the trouble with the South is lack of business methods and lack of appreciation of changed conditions and opportunities. Other causes have operated in the same direction. The clean cultivation of cotton has caused a great oxidation and loss of organic matter, leaving the soil poor in the organic substances necessary for the normal weathering of the soil, which would make the plant food available. In many areas it has also caused destructive erosion. Climatic conditions unfavorable for grain crops have also prevailed. The normal yield of grain in the South is about one-third of what it is in the North, probably because the greater humidity favors extensive leaf development at the expense of seed. (871-873.)

B. Principal methods of maintaining fertility (see also *Intensive and extensive culture*, VII D, p. cxciv).—1. *Practice in various places.*—*China.*—Professor KENZIE, of the Michigan Agricultural College, says that according to Chinese tradition the soils of China have been in continuous cultivation for more than 4,000 years; but they are still rich and productive, because everything is returned to the soil. The excrement of every kind of animal and of human beings is saved as if it were gold, to go back upon the land, and the consequence is that the soil has not fallen off in productiveness. (540.)

France and Germany.—Mr. DYE says that in Germany and France fertilization by means of root and other crops and manure has been practiced for more than a century with great advantage. (93.)

Dr. WILEY says:

"Fifty years ago the yield of wheat in northern France—and that is the granary of France—was about 17 bushels to the acre. To-day the average yield of wheat on these same fields is 23 bushels to the acre. Now, there is a system of agriculture which increases the yield of the crop and at the same time enriches the soil. The soil of France, to-day, is more fertile than it was at the time of Cæsar, and will produce a larger yield."

Dr. Wiley attributes the increase to improvements in scientific agriculture made in the last 50 years. While the land of Germany is not so rich, and the yield not so large, the increase has been proportionately as great. (648.)

New England.—Mr. BATCHELDER says the more progressive farmers of New England are taking special pains to maintain the fertility of the soil. The Grange and other organizations have paid special attention to the use of different kinds of fertilizers, and have encouraged farmers to experiment with them. (41.)

New Jersey.—Mr. KETCHUM thinks the productive condition of the soil is being kept up on most of the farms in New Jersey. (135.)

Mr. DYE says that in New Jersey, as long as 40 years ago, many of what had been considered the best lands had been abandoned to pasturage on account of exhaustion, but by the use of improved methods these soils have been restored to fertility.

Michigan.—Professor KENZIE mentions a farm in Michigan which has been cultivated for 40 years, with constantly increasing fertility, without a pound of commercial fertilizers. Only finished products have been sold from the farm. The hay, corn, corn stalks, and all coarser material have been kept and fed to the stock, and only the stock, wool, butter, cheese, and occasionally a little wheat, have been sold. (549.)

Illinois.—Mr. GEORGE thinks the soil of Illinois, where it has been properly managed, is more fertile now than when the prairie was first broken, and that this promises well for the perpetual productiveness of the West. (223.)

Mr. WILSON testifies that there has been no decline in the producing capacity of the soil in northern and central Illinois, and he thinks there is none in southern Illinois. In central Illinois there is an increase rather than a decrease, due to rotation of crops, cultivation of clover, careful till'ng, and use of fertilizers. No commercial fertilizers are used in the State, so far as he knows. Many farms have been increased in productiveness one-fourth, and some one-half, merely by tilling. (249.)

North and South Dakota.—Mr. BUDGE says there is no decline in the productive power of the soil of North Dakota if it is handled rightly. The soil in the Red River Valley is black loam to a depth of about 1 foot to a foot and a half, with a heavy clay subsoil. Outside of the valley the soil is lighter. As a rule, the soil has not been fertilized. Mr. Budge fertilized one piece of ground close to town, and raised 36 bushels to the acre on it. Improved farming and careful management are growing

in favor. A good many farmers rest one-third of their land while they cultivate the other two-thirds. (849, 850.)

Mr. PROM says the soil of North Dakota is not declining in productiveness if it is taken care of, and it is being taken care of. There are farms that have been sowed to wheat for 15 years in succession; that is hard treatment, but the last year's production was wonderfully large, showing great strength and richness of the soil. The soil is a rich, black, heavy clay loam, about 24 inches deep, on a clay subsoil. It is easily brought up when run down. The only way it is rested is by summer fallowing—laying it over one year and letting weeds grow, then turning them down in August before they go to seed. Clover is not raised. (791.)

Mr. GREELEY, of South Dakota, says the very large farms are running out, but a few of the farmers are maintaining the productive condition of the soil by keeping stock and rotating crops. Clovers can not be raised to any great advantage in the Dakotas, but in Minnesota the clover plant ranks with the stock in keeping up fertility. (937.)

Virginia.—Mr. WEDDERBURN thinks that where the soil of Virginia has been properly cultivated and fertilized the yield is larger than it has been in the past. He knows from his own experience that it is possible to increase the yield largely by proper cultivation and fertilizing. (622.)

Kentucky.—Mr. NALL does not think there has been any very great decline, on the whole, in the productive condition of Kentucky soils, generally speaking. The fertility has been kept up to about what it was 30 years ago. (811.)

2. *Rotation of crops.*—Mr. WHITNEY says there is no question but that, in general, a rotation or change of crops is of value in preventing undue waste of certain elements of plant food and undue tendency toward a particular manner of cultivation, yet in some instances a single crop has been grown on the same land for many years without any apparent deleterious effect, as on the eastern side of the Connecticut River, near Hartford, where the broad-leaf tobacco has been grown continuously for 25 years, and the yield and quality are claimed to be as good as at the beginning, or better. The land, however, is fertilized. (874, 875.)

Mr. Whitney adds that clover is one of the best renovators of the soil where it can be grown, but the most generally useful crop is the cowpea of the South, which is now being used to a considerable extent in the North. (883.)

Mr. Whitney refers to the enormous yields of potatoes obtained at Greeley, Colo., where rotation is practiced. (884.)

Mr. GEORGE testifies that clover, blue grass, or timothy, in rotation with other crops, increases the fertility of the soil. Clover does not grow in the Southern States, but for the Northern States there is nothing equal to it. The thick foliage shades the soil and prevents its rapid decomposition. It also takes nitrogen from the air and deposits it in the soil. (223.)

Mr. DILLINGHAM believes in the cultivation of leguminous plants, such as beans and peas, in the South. (169.)

Mr. COLES, of Salem County, N. J., explains the local custom as to rotation of crops to be as follows: The first year fertilizers are used and potatoes are planted; the potato crop pays for the fertilizer. Potatoes are followed first by wheat, and then by clover and timothy, which are mowed the first year and generally used for pasture the second year. Where there is plenty of stock the land is improving. It does not improve very much with the fertilizer alone. (128.)

Professor DAVENPORT testifies that there is a piece of land at the University of Illinois on which corn has been produced continuously for more than 20 years without fertilizing, and the yield per acre is only about 50 per cent of that of other unmanured land which has been devoted to diversified farming. The cost of raising corn at the institution varied in 1898 from 15 to 45 cents a bushel, according to the previous treatment of the land. (260.)

Dr. CROWELL says the custom of plowing in clover for fertilizing the soil, practiced among the Pennsylvania Dutch, is also growing very rapidly in North Carolina, in the Piedmont section as well as in the eastern section between Raleigh and Goldsboro. He thinks this might be done, with clover or some substitute for clover, in all parts of the United States. (335.)

Mr. GRAHAM says the farmers of North Carolina have improved their methods within a few years, and large areas have been sown in pease, not only for forage, but to improve the land for the cotton crop. This has reduced the amount of fertilizers needed. The pease supply the ammonia, and it is a simple matter to supply the phosphoric acid and potash. (433, 434.)

Mr. NALL says the Kentucky farmers have increased their wheat yield by the use of stimulants, such as phosphate, etc., and that gives a chance to improve the land by some leguminous crop. Stock pease are used, and lately the United States Depart-

ment of Agriculture has introduced a legume known as the soy bean, which the people are beginning to like very much as a forage plant and renovator of the soil. It grows vigorously on poor land, and the experiments with it have been very satisfactory. (811.)

3. *Culture of soil bacteria.*—Mr. WHITNEY says that leguminous crops have tubercles on their roots containing large numbers of bacteria, and by inoculation pure cultures can be made. Such cultures are for sale in Germany, and to a limited extent in this country. Many of the leguminous crops, e. g. clover, will not grow unless these bacteria are in the soil, and by sowing pure culture over the land the yield may be doubled or more than doubled. It is only within 30 or 40 years that the soil bacteria have been recognized and their importance understood. (882.)

Mr. Whitney says the newly discovered nitrogen is really a pure culture of bacteria, which by their activities in the soil have rendered the plant food available by increasing the weathering, and also added nitrogen from the air. (874.)

4. *Artificial supply of needed elements of plant food.*—Professor KEDZIE says that exhausted fertility can be restored to the soil to some extent by leguminous plants, but lost potash and phosphoric acid must be returned by some form of commercial fertilizers. There is a natural development of fertility by the chemical changes which take place in the soil under natural conditions, making the elements of plant food more and more available; by adding to this the fertility of the soil may be built up. (549.)

Mr. WHITNEY says that the primary object of fertilization is the adaptation of soils to any desired crop or crops. Frequently the natural fertility is so low that it is unprofitable to raise a particular crop. Frequently, again, even on very rich soil, the aim is to force the crop, a process which Mr. Whitney compares to the fattening of stock with concentrated food. This is done especially with truck crops. The effect of fertilization is, first, the addition of plant food to the soil in such a form that the crops can immediately use it; secondly, an increase of decomposition of the soil particles—that is, an increase in the weathering power.

One object is to improve the texture of the soil. Frequently a wet clay can be made more pliable and the drainage improved, or loose soil may be made more compact and retentive of moisture. At times, again, the fertilizers balance the ratio of soil constituents. In Maryland and in Pennsylvania there are small areas of soil derived from the disintegration of serpentine rocks, carrying a large proportion of magnesia, on which the application of lime sufficient to reverse the ratio restores the fertility. Again, soil is frequently acid. The soils of Rhode Island are very generally so, and the addition of lime neutralizes this acidity and promotes fertility in a very marked degree. Acidity of the soil is much more prevalent than has heretofore been supposed. (874.)

Limitations of soil analysis.—Mr. WHITNEY says one can not ordinarily tell simply by the examination of the soil what is required to make it more productive. That is a very embarrassing question to answer, because deterioration is quite as often due to lack of good management on the part of the farmers as to chemical or physical causes. The kind of crop a soil is adapted to can often be determined, but the chemical analysis does not clearly indicate whether it is fertile in its existing condition. (882.)

Mr. CLOHAN has had samples of soils analyzed, but does not think soil analysis yields practical results, because there are so many different conditions in one field. He thinks the character of soils can be determined by the eye. Where there is a luxuriant growth there is an abundance of nitrogen in the soil; if the fruit does not color well potash or phosphoric acid is needed. (595.)

C. *Fertilizers.*—1. *Muck.*—Mr. WHITNEY thinks that it would be feasible to reclaim some of these so-called worn-out farms of Maryland and Virginia by the application of muck from the low places, but the cost would be too great unless these low places were adjacent to the land to be treated. The cheapest methods in other cases is to grow cowpeas and other green crops, which are sure to improve the land. (883.)

2. *Horse manure.*—Mr. AGER, master of the Maryland State Grange, says that the price of manure in Washington, D. C., is about 75 cents to \$1 for a 2-horse load. When a farmer pays \$1 a load and hauls it out, he is paying a pretty good price, for, according to Professor Voorhees, of the New Jersey Experiment Station, the average ton of horse manure does not contain more than 28 pounds of plant food. With the improved stables the liquid portion goes into the sewer, and about all the farmer gets is dirty straw. Mr. Ager believes that if gardeners would work less land at a time and enrich their land with leguminous crops, they would make more money than by hauling so much manure. (106.)

3. *Use of commercial fertilizers in various localities.*—*Massachusetts.*—Mr. STOCKWELL

says that the Massachusetts farmers, having been educated by the farmers' institutes and otherwise, now buy the needed elements of plant food very carefully, and do not waste money on fertilizers. (895.)

New Jersey.—Mr. COLES, of Salem County, N. J., testifies that commercial fertilizers are used a great deal in that section. (127.)

Ohio.—Mr. MILLER estimates that there were sold and consumed in Ohio in 1899 fully 200,000 tons of commercial fertilizers. The average cost to the farmer was about \$17 a ton. Fertilizers are very much used in some sections of the State, and very little in others. Mr. Miller's estimate for 1896 was 150,000 tons, showing an increase of 33½ per cent in 3 years. (611.)

North Carolina.—Mr. WHITE testifies that commercial fertilizers are used a great deal in North Carolina near the cities and towns, but in the remote rural districts composts and lime are used. (423.)

Lower Mississippi Valley.—Mr. KYLE, of Mississippi, testifies that no fertilizer is used in the Delta, and very little in the hill country.

Fertilizer policy for the South. (See also *Methods of intensive culture without commercial fertilizers*, VII D 2, p. cxcv.)—Mr. HALE declares that far too little fertilizer is used to the acre in the South, and that the use of low-grade fertilizers is a very serious hindrance to successful agriculture. The South does not understand the economic value of using the highest grade, and high prices are charged for inferior goods. (380.)

Western States.—Mr. WHITNEY says the farmers of the West are not using fertilizers to any great extent, though the practice has increased a very little. (883.)

4. *Effect upon the yield.*—Mr. COLES, of Salem County, N. J., testifies that farmers in that section do not use more than 700 or 800 pounds of fertilizer to the acre for early potatoes. With this treatment there should be from 150 to 200 bushels an acre. The first potatoes are sold for about \$3 a barrel of 2½ or 2¾ bushels, prices ranging from there down to \$1 a barrel, and sometimes lower; the average for the season is not much more than \$1.50. At these prices early potatoes are a profitable crop in a good season. (128.)

Mr. LOVEJOY, of Georgia, believes that if the farmers would put the same amount of money into making a fertilizer that they put into commercial fertilizers, the results would be better. (79.)

In Mr. HAMMOND's opinion the fertilizer business has been an unmitigated curse to the South. The people have been led to pay out their money for fertilizer when they ought to have kept stock and made their own manure upon the farm. (834.)

Mr. WHITNEY agrees with Mr. Hammond that the use of fertilizers tends to make the farmer less careful. (882.)

Mr. AGER testifies that some of the farmers of Maryland have used nitrate of soda on their hay crop. The use of 100 pounds of nitrate of soda to the acre, just as the grass was starting, has often increased the crop 1,200 to 1,500 pounds per acre. (108.)

Mr. WEDDERBURN says he has a little property within 12 miles of Washington, formerly pine land. After cutting down the pines he fertilized liberally with phosphate and potash and leaves and muck, and can produce a very good crop. Other men who raise wheat in Fairfax County have done the same thing and produced as high as 30 and 35 bushels to the acre. A still better system would be to sow the land to black-eyed peas, rye, or other green crops, to improve the land. A Government employee bought a field of 30 acres adjoining Mr. Wedderburn's land, fertilized it, set out fruit trees, and planted crimson clover and peas between the trees, and in 4 years had a magnificent orchard. (622.)

Mr. POOLE, Commissioner of Agriculture of Alabama, says that where lands are not fertilized they deteriorate very much, but the productiveness of the Alabama soils has been increased by the use of fertilizers. Lands which 25 years ago were not producing a bale of cotton to 5 acres now make a bale to the acre. (924.)

5. *Composition and sources of supply.*—Mr. HALE explains that a complete fertilizer contains phosphoric acid, potash, and nitrogen. The phosphoric acid comes largely from the South Carolina rock phosphate, which is probably the cheapest source of phosphate in the South. In the South the nitrogen is supplied by cotton-seed meal, but it is a low grade of fertilizer. Nitrogen is the most expensive element of plant food, costing from 16 to 20 cents a pound, against 5 cents for potash and kainite and 7 cents cents for phosphoric acid. (380, 389.)

Mr. MILLER says the sources of supply of fertilizing ingredients are mainly Chicago, Omaha, and Kansas City for animal substances, and Florida, South Carolina, and Tennessee for minerals, while the potash comes wholly from Germany. Fertilizers are manufactured more largely on the seacoast than in any other particular part of the United States; next in order, perhaps, would be Chicago, the cattle center. (611.)

Mr. HAMMOND, of South Carolina, says that the phosphate industry of his State

has declined in recent years because of the discovery of the Tennessee and Florida phosphates. (834.)

Dr. STUBBS says that the fertilizers which are used very largely in sugar cane culture in Louisiana are usually nitrogenous—cotton-seed meal and tankage (refuse from slaughterhouses), with small additions of acid phosphate. Dr. Stubbs explains that everything that can not be used otherwise in the slaughterhouses is put into the refuse house, and after the oil is extracted from it the residual tankage, consisting usually of scrapings, blood, bone, meat, hides, and hoofs, is sent down to be used as fertilizer. Condemed animals are used for soap, not for tankage. Dr. Stubbs understands that the saving of tankage constitutes a large part of the profit of slaughterhouses. (774.)

6. *Prices of fertilizers.*—Mr. MILLER, of Ohio, says there has been no marked difference in the price of fertilizers in Ohio since 1895. There was a little increase on certain ingredients in 1899, but the phosphates have been growing a little cheaper because of the enlarged territory from which mineral phosphates are derived. (611.)

Mr. GRAHAM believes that the advance in the price of fertilizers can not be due to anything but a trust. The raw material is controlled wholly or in part by the companies making the fertilizers. At the time of his testimony Mr. Graham was on a committee which expected to be able to show that the companies owned the phosphate rock. Potash is imported 12 months ahead from Germany. The price of fertilizers was suddenly advanced from 15 to 25 per cent early in 1900, although there is 50 per cent more phosphoric rock apparent in the world than was ever known before. The price is higher in Wilmington than 100 miles inland. The prices are arranged according to the competition. Mr. Graham enumerates a number of fertilizer works in North Carolina, and says the Acme works at Wilmington are independent. (437.)

7. *Fertilizer laws.*—*Massachusetts.*—Mr. STOCKWELL says it was the Massachusetts Experiment Station which first showed how the farmers were being cheated in fertilizers. The law on that subject, which was the first of its kind, was secured under the lead of Dr. Goessmann, and has been followed by many other States. (894.)

Ohio.—Mr. MILLER says the law of Ohio provides that manufacturers and dealers in commercial fertilizers shall apply annually for licenses and pay fees of \$20 for each brand offered for sale in Ohio. The license is issued by the secretary of the State Board of Agriculture. Each package offered for sale must be tagged to show the amount of nitrogen or its equivalent in ammonia and of phosphoric acid and potash. There have been several prosecutions under the law, but no convictions, because the manufacturers in every case have paid the penalty and promised to be good. (611.)

Mr. Miller, as secretary of the Ohio State Board of Agriculture, is charged with the duty of analyzing commercial fertilizers, and not being a chemist he employs Professor Lord, of the Ohio State University, to make the analyses. Deputy inspectors of commercial fertilizers are constantly traveling over the State and securing samples from the open market and from the consumers for analysis in comparison with the samples submitted by manufacturers when applying for licenses. The actual amount of different ingredients in each fertilizer is published and the report widely distributed. (610.)

Alabama.—Mr. POOLE testifies that there is a tax of 50 cents a ton on fertilizers sold in Alabama. Before offering his goods for sale the manufacturer applies to the Commissioner of Agriculture for tags, filing an analysis of his fertilizers, and the tags are supplied to him at the prescribed rate. The State Chemist at the agricultural college at Auburn analyzes all the fertilizers offered for sale, thus securing to the farmers the genuineness of the goods offered. On every sack of fertilizers is an analysis showing its constituents. The receipts from the tag tax are steadily increasing and now amount to about \$100,000 a year. (920.)

Desirability of uniform legislation.—Mr. WHITNEY alludes to the rather stringent laws governing the inspection and sale of fertilizers in most of the Eastern States, and says the subject has been taken up by the Department of Agriculture with the idea of having a more uniform system of laws, if possible, and of having national laws for the interstate trade. (874.)

8. *Sewage and garbage.*—Mr. DYE believes that sewage and garbage from cities would be of very great advantage if utilized upon the land. (93.)

Sewage irrigation a subject for future investigation.—Mr. WHITNEY, chief of the Bureau of Soils in the United States Department of Agriculture, says he has never investigated sewage irrigation except quite incidentally. (883.)

D. *Intensive and extensive culture.*—1. *Economic considerations.*—Dr. TRUB explains the success of the British farmer, notwithstanding the high rentals paid for land, by the nearness of the market, and by the farmers having learned by experience the necessity for careful culture. (144.)

Dr. CROWELL thinks that as a rule American farmers have adopted intensive methods as fast as the demand has justified. They would not succeed if they put as much capital into the land as the English farmer does. (341.)

Mr. WHITNEY says there will be danger of the soils of the West becoming barren if the owners persist in cultivating the same crop year after year, as is now done in the Red River Valley and in some of the Central States; but by rotation of crops or by more intensive methods when the soils begin to wear out their fertility can be maintained and improved. The Western farmers say, very justly, that while they are getting 12 or 15 bushels of wheat to the acre at a cost of 20 cents a bushel they do not care what becomes of the land; it is going to last the lifetime of the present generation and they are not concerned as to what becomes of it afterwards. Mr. Whitney thinks it likely that a yield of 12 or 15 bushels can be maintained in the Red River Valley for a long series of years. The soils are almost identical with the fertile wheat lands of Russia which have produced wheat for many generations. Yet he predicts that the time will come when the yield will be less than now and when the farmers will feel the need of fertilizing the soil better or of changing the crops and introducing more intensive methods. With reference to present conditions he says that farmers can not spend much money in maintaining the fertility of cheap lands. It is an economic question, not an agricultural one; they can not afford the expense of maintaining the fertility of these lands until the lands become more valuable. (883.)

Mr. STEVENS testifies that intensive farming is claiming the attention of the people of Georgia more than heretofore, and the utilization of manure has increased, with a favorable effect on production. Wages are increased because crops are more directly profitable. (915.)

2. Methods of intensive culture without commercial fertilizers.—Mr. WHITNEY says that the lands of Eastern countries have been cultivated for hundreds and thousands of years. The farmers have saved all of the litter, excrement, and waste of the farm and put them back on the soil. They have had small holdings and use intensive cultivation. We use large areas—too large to manure with the ordinary waste from the farm—and rely upon commercial fertilizers, which have been introduced comparatively recently and are lacking in organic matter. Mr. Whitney thinks that much harm has been done by constant and excessive use of commercial fertilizers without the intensive methods which should be employed with them. (882, 883.)

Thorough tillage.—Mr. HALE contrasts a farm of 40,000 acres in the Sacramento Valley, where 8 furrows at a time are turned over by gang plows run by steam, with a little corner of 500 acres taken out of the same farm and owned by a woman, which is plowed by a single team of mules, harrowed and cross plowed, and again harrowed and smoothed down. For a number of years the average yield of wheat has been 15 bushels an acre on the large farm and 35 bushels on the small farm. No fertilizers are used in either case. (392.)

Raising of tobacco and pineapples under cover.—Mr. WHITNEY testifies that even with the initial expense of \$500 an acre for covering the field with cheesecloth, the profit from the cultivation of Sumatra tobacco in the Connecticut Valley is likely to be large. A crop of \$1,400 worth is expected this year (1901) from an experimental plot of one-third of an acre. The same method has been used very successfully in the cultivation of pineapples in Florida, to protect them against frost, and seems to be coming into very extensive use in intensive farming; e. g., for the protection of truck crops from the frost and from drought on sandy soils. It is the intense heat of the middle of the day that hurts tender vegetables, unless they have plenty of moisture. When under cover they have a diffused and less intense sunlight. (876, 877.)

E. Size of farms.—**1. Size of farms in various localities.**—*New Jersey.*—Mr. COLES estimates the average size of farms in Salem County, N. J., at a little less than 100 acres. (130.)

West Virginia.—Mr. CLOHAN, of West Virginia, says that in Berkeley and Jefferson counties a farm of 300 acres is counted a large farm. Some of the farms are being divided up into smaller ones. (593.)

Georgia.—Mr. HALE says there is no bonanza farming in Georgia, though there are some large cotton planters and some very large fruit and vegetable farms. (390.)

Mr. STEVENS says no particular number of acres is required for a farm in Georgia. Forty acres can be cultivated with 1 horse or 1 mule, and 80 acres is usually regarded as a 2-horse farm. The farms run all the way from 1 to 100 plows; Mr. Stevens himself has run 100 at once. The land is usually a light, loamy soil that is easily cultivated. (910.)

Alabama.—Mr. DILLINGHAM, of Alabama, says the average farmer in his neighborhood has about 25 acres and raises about 8 bales of cotton, or on an average a little less, which, with a little corn, represents his total income.

Southern States.—Mr. POWERS says farms are as large in the South as they are in the North, outside of the great grain-raising country. The South formerly had more large farms than the North, but many of the original large plantations are now divided up into a great many small ones. (171.)

Tennessee.—Mr. HILL, of Memphis, says that land in that vicinity is not owned in large tracts as much as formerly; it is being cut up into smaller farms. (503.)

Mr. NORFLEET, of Memphis, says there are a good many large plantations in that vicinity. By a large planter he means one who makes 600 to 2,500 bales of cotton. In the delta the planters make an average of about 10 or 12 bales of cotton to the mule; for 1,000 bales of cotton they use something like seventy-odd mules. (488.)

Mississippi.—Mr. NORFLEET testifies that the negro can maintain his family splendidly on 40 acres of Mississippi bottom land. They do not cultivate as large an acreage in the Delta as on the hills. (486.)

Mr. KYLE says the land of Mississippi is still owned in large tracts, though in many cases not so large as before the war. That section of the country was formerly owned by large planters having large numbers of slaves; since the war the lands have been divided up. (465.)

2. Advantages of the small farm.—There is no question in Mr. POWERS' mind that small farms are better than large farms. Where one man can direct the labor of others wisely, there are ten men who can direct their own labor wisely. (187, 188.)

Mr. GEORGE thinks small farms have an advantage over large farms in more thorough cultivation and are more successful. Large farms are usually farmed in a slipshod manner. (221.)

Mr. WILSON considers small farms a benefit so far as school advantages and social advantages are concerned, and also a great benefit to the country at large. He thinks the large farm has no advantages over the small one; the small farmer is the only one he knows of who has made any money of late. (249.)

Mr. POOLE says the smaller farmers in the sandy counties of Alabama are more progressive than the large farmers. Mr. Poole thinks that if the farmers could be induced to sell off their lands in smaller tracts (than 320 to 2,000 acres) it would be much better for the country as a whole, but the person who owns property paying from 10 to 15 per cent on the investment is very loath to part with it. (921, 922.)

Mr. GREELEY, of South Dakota, says there is still a good deal of unoccupied land in that part of the country, and often one man has too much land. When he has a great deal too much the superabundance generally ruins him, and the land is then distributed properly. When the farms are smaller, the yield and the population can be doubled. (930.)

Mr. HAMMOND, a cotton planter of South Carolina, declares:

"I know of no record in history where a race of small proprietors has been prosperous. Everywhere they seem to form the wretched residuum of labor after all other occupations are supplied." (840.)

3. Bonanza farms.—Mr. BRIGHAM says the competition of Western farmers with the East has been a serious injury, but bonanza farmers do not compete more injuriously than small farmers would do. Many of the large farmers of the West lose money. They exhaust the soil and fail to take advantage of the rotation of crops. (17, 18.)

Mr. JONES adds that owing to the tendency of bonanza farmers to produce only one crop, subdivision of their farms might lessen competition in that particular product, but it would increase the pressure of competition as to other products, so that there would be no material difference. While production on a large scale is economical in manufacturing, the intense application and personal interest of the farmer as to his own farm make small farming more economical than bonanza farming. (38.)

Mr. WILSON testifies that Sullivan's farm in Ford and Champaign counties and other bonanza farms in Illinois have been broken up, but he thinks the size of the ordinary farm has increased in the last 25 years. (249.)

Mr. BUDGE says there are several big farms in North Dakota, and mentions one of about 7,000 acres. He adds that he would like to see them all out of the way. They take up so much space that they hurt the school districts. The owners ship in their supplies and ship their wheat out, and ship their men in and out. The plowing is done with gang plows, and 4 horses or mules to each plow. One man with such a team can plow about 5 acres a day, or with good soil a little more. Gang plows operated by steam have been tried, but do not work. One man can handle 160 acres on a farm of that kind. The employees are generally single men. The farm owners hire a crew in the spring and let them go in the fall, except one or two to take care of the farm. Mr. Budge thinks some of the big farms are profitable and some are not, depending on how they are handled. The land has grown in value, and money is made in that way. He mentions in particular the Grandin and Dalrymple farms as having made money. (850, 851.)

Mr. PROM says the effect of bonanza farming is not good. The bonanza farmers do not patronize the villages, but ship in goods from the East, and act as wholesale grocery houses for themselves. They are also probably a drawback in the way of school privileges, which they do not need, and if there are small farms wedged in between bonanza farms the occupants suffer. The bonanza farms are divided up into different parts, with a foreman for each part. Each has a little village of its own. The hired help are usually single men; only the foreman is married. The bonanza farms are well conducted upon strictly business principles, the farming is done more scientifically and economically than on the small farms, and the percentage of profit is larger; but the general results to the people of the country are not good, and the people would generally favor the abolition of bonanza farming. (791, 792.)

Mr. GREELEY, of South Dakota, considers bonanza farming a curse to the country and to the man who tries it. If carried too far, after the population gets more dense, it will keep thousands of men from having homes of their own. It employs men in squads, thus eliminating their individuality and independence. Those employed on these farms have to work with the worst kind of men. The soil is abused, and then goes to other people in small holdings to be built up by careful rotation, stock farming, and tillage. The bonanza farms are owned largely by men who spend their money in the cities or in other States. They rob the public schools, and detract much from the social life of the country. Mr. Greeley does not know of one very large farm that has been running for some time that is now paying, and says bonanza farming is on the decrease. (934.)

Mr. HANLEY considers the bonanza farm a detriment to the community, and believes that they are profitable only because of advantages in the direct shipping of grain. (279.)

Mr. DYE, of New Jersey, believes that the subdivision of bonanza farms into small tracts would be beneficial by increasing the population and giving employment to more people. The opportunity to use improved machinery on a very large scale on these farms tends to make their competition disastrous to Eastern farmers. (94, 96.)

Mr. POWERS says all the big farms, including the Dalrymple farm in Dakota, are in the market for breaking up, just as the big farms of southern Minnesota have been cut up. (188.)

F. Reclamation of swamp lands.—1. Tide marshes.—Mr. WHITNEY says it is estimated that there are 168,000 acres of tide marshes along the Atlantic and Gulf coasts and several million acres along the Pacific coast, which, if protected from the tide and drained, would be of value in agriculture. Marshes have also an effect upon the value of adjacent land because of the prevalence of mosquitoes and disease. The Department of Agriculture has been applied to recently from many sources to suggest means of reclaiming the tide marshes and inland swamps of the United States, partly for their agricultural value and partly for the increase of healthfulness of the surrounding land. Malaria and similar diseases have contributed greatly to the discomfort of many of the Atlantic coast States, and in many cases areas and industries have been abandoned because of the unhealthfulness of the neighboring marsh lands. These causes have prevented to a large extent the settlement of some of the Southern States, and have caused the abandonment of other lands. (864.)

Mr. Whitney says it is desirable to reclaim the swamps of the Atlantic and Pacific coasts not only for their great agricultural value, but for the welfare of the surrounding country. Certain portions of the city of Washington, for example, have been rendered almost uninhabitable by the conditions prevailing. There should be a levee with gates to let the water out which would shut when the tide comes up, as in the rice lands of the South. This protection, together with the necessary drainage of the soil itself, would reclaim the land, and an appreciation of property aggregating thousands and thousands of dollars would result. It has been estimated that the reclamation of the marsh lands adjacent to Jersey City would cost about \$3,000,000. The plans for this work are under consideration, and the reclamation of large areas has already been undertaken. The disastrous effects of the swamps are keenly felt by summer residents along the coasts of Long Island, New Jersey, Delaware, Maryland, North Carolina, and Virginia. Besides being unpleasant, the mosquitoes carry malaria, and other fatal fevers are prevalent. (881.)

Mr. Whitney says a plan has recently been proposed to the Department of Agriculture for the reclamation of a large area of swamp land in Long Island, in order to treat the swamp for mosquitoes and control the malaria, and it is probable that that plan will be carried out. (881.)

Mr. Whitney predicts that legislation will be necessary in the case of the marsh lands of Marshfield, Mass., and that their reclamation is likely to be a complicated

OXOVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

matter. It is a matter concerning the State rather than the National Government, unless it should interfere with the channels of the harbor. (882.)

It seems to Mr. Whitney that the drainage of swamps for the purpose of controlling mosquitoes and preventing malaria is work primarily for the individual and secondly for the State, not for the National Government. It is unlike the development of harbor privileges and the improvement of rivers in that it affects to the locality in which it is conducted. (881.)

2. Inland swamps.—Mr. WHITNEY says that many areas of swamp lands and some large areas of cold, wet clays are unproductive or have been abandoned because of a small accumulation of water which needs only to be removed by some artificial means. It is estimated that one-fifth of Michigan is swamp land. During the year 1893, 26,985,000 feet of tile drains were laid in Illinois, mainly in the northern and central parts of the State, where there were 28 or 29 feet of tile laid to each acre cultivated. In Douglas County there were 85 feet and in Livingston County 78 feet to each acre cultivated. As late as 1880 lands could be purchased in the Vermilion Swamp in Livingston County for from \$3 to \$5 per acre; since these lands have been drained they are valued at from \$60 to \$90 per acre for general farm purposes. As a result of the widespread drainage in Illinois and Michigan, the swamp lands have become most productive, the health of the region has been much improved, and the public roads have been kept in much better repair. (880.)

Mr. MILLER says Ohio has very ample drainage laws, executed by township trustees and county commissioners, which have been almost universally availed of in parts of the State requiring drainage. The county incurs a considerable part of the expense in paying the engineers, commissioners, and trustees; the remainder is raised by assessment according to benefits, deferred payments being placed on the tax duplicate as other taxes are. Money is raised at the time by selling bonds, though in many cases the counties are able to pay the expenses outright, and collect on the tax duplicate afterwards. The State Board of Agriculture has from its organization published important papers and lectures on the subject of drainage. Ohio has no very large amount of unreclaimed swamp lands. (608.)

3. Need of drainage in the West.—Mr. WHITNEY testifies that soil investigations in the Salt Lake Valley have shown that it would be possible to reclaim a large tract of salt land west of Salt Lake City, and that perhaps this should be done; but the State is debarred by its constitution from taking any part in internal improvements, as is done in Minnesota and some other of the Central Western States, and by reason of the lack of drainage laws it would be almost impossible for the landowners to drain any considerable part of the area without the written consent of every individual land owner affected. In the attempts that were made it was not found possible to get such consent. (880, 881.)

It seems to Mr. Whitney that drainage legislation is one of the important problems for the Western country, where some remedy must be found for the accumulation of seepage water and alkali from leaky ditches and overirrigation, either through State or national legislation. Land owners should be given recourse for the recovery of damages in civil suits, in case of such injury by seepage. (880.)

G. Forestry.—Mr. WHITNEY says that another important means for the reclamation of poor or abandoned lands is the reforestation and protection of timber from fires and a more rational method of cutting timber. This is one of the important remedies applicable to areas in which there seems at present no other mode of improvement. (878.)

1. Relation of forests to the water supply.—Mr. HAMILTON explains that a forest acts as a reservoir, preventing the water from flowing off; it percolates into the soil and fills the river gradually, continuing the flowing of springs and streams during the entire season. The deforesting of a district takes away its reservoir character, so that the water that falls runs off nearly at once into the streams, resulting in destructive floods, while a slight drought dries the streams up. (363, 364.)

Mr. GREELEY testifies that only a few years ago there were whole counties of pine and hemlock at the headwaters of the Mississippi and its tributaries, under which there were deep mosses from 6 inches to a foot deep. Mr. Greeley has seen snow and ice in this moss in shady places as late as the middle of June. The snow melted slowly, and it took months for the water to ooze through the moss and deep surface loams. Millions did not have to be spent to ward off floods, nor did the streams nearly dry up as they do now. Vast regions which were thus protected have been stripped of the pine and hemlock, and the slashings burned over, until now one hot March day sends a winter's snow rushing into overflowing streams. (944.)

Mr. NAFTZGER says the preservation of the forests on the Pacific slope, and particularly in California, where there is so much irrigation, is of vital importance. The

destruction of the forests destroys the water storage, and also reduces the rainfall, according to very competent engineers. (966.)

2. Purposes and methods of forestry.—Professor FERNOW, director of the New York State College of Forestry, defines forestry as the business and art of producing wood crops and deriving a revenue therefrom. It implies a continuous succession of profitable forest growth from which profit may be continuously derived, just as profit is continuously derived from the use of the soil for food crops. The forester differs from the lumberman chiefly in that he has regard to the future, as well as to the present, and sacrifices some present profit to the future welfare of his forest. On account of the long time which the crop requires to mature, from 50 to 100 years and more, the business is not suitable for the small capitalist. The farmer can profitably practice sylviculture on his wood lot, according to the principles outlined in Farmers' Bulletin No. 67, United States Department of Agriculture, entitled *Forestry for Farmers*. But the farmer's wood lot is not suitable for the production of log timber. It is fit only for growing firewood, posts, and poles of small dimensions. Log timber must be grown on large contiguous areas by large capitalists, who can afford to have their capital tied up for a long time, and are not tempted to cash it as soon as it becomes possible. Forestry affords a safe continuous investment, with sure, though comparatively small, returns. It is peculiarly a business for States and communities to undertake. (1001, 1002.)

Mr. Fernow says that so long as virgin supplies of timber, which have cost nothing to produce, compete in the market, there is little inducement to apply money to the production of wood crops. The time seems to have come, however, when those who now begin to look out for the future may expect to reap their reward. This is especially true of certain kinds of timber supply, such as pulp wood. (1002.)

Mr. Fernow says that the most difficult problem in the management of forests is protection against fire and getting rid of the debris that comes from logging, when the brushwood can not be disposed of. Attempts to utilize the brushwood have not so far succeeded financially. Constant patrol seems to be the only help against fire. All other means seem to be more expensive and less effective. (1004.)

3. Forestry in Germany.—Mr. HAMILTON thinks that some large owners of timber lands select trees to cut so as to keep the growth about even, allowing the rest to grow, and when that matures, cut it all off and reforest. The German method is to take out at first the better portions and allow the rest to grow for 30 or 40 years. The forest is then nearly uniform, and is allowed to grow for another 30 or 40 years, when it is fully matured and the entire section is cut off and reforested. The German foresters plant trees of high value, mostly the conifers, and they also plant trees of inferior quality that will grow up among the cone-bearing trees and prevent the growth of lower limbs upon the latter. After a while the inferior trees are cut out and the others allowed to grow. (365.)

Mr. Hamilton states on the authority of a recent official report that the German Government receives annually about \$95,000,000 from forests, of which about \$55,000,000 is clear profit. There are many districts where no taxes whatever are levied, the forests supplying all the revenues for schools and roads. (364.)

4. Forest lands of New York State.—Mr. FERNOW, director of the New York State College of Forestry, states that the forest commission of New York State was established in 1885 to take charge of the forest reservations in the Adirondacks, amounting at that time to some 800,000 acres. The State now controls about 1,500,000 acres. The commission exercised the power to cut timber by selling stumpage to lumbermen, and the woods continued to be culled of the valuable spruce and pine, just as before. This led to the insertion of a clause in the constitution which forbids the cutting of any trees on the State lands, as well as the building of railroads over them. This clause prevents the application of forestry to the State lands.

For the purposes of a demonstration on a small scale, showing how a forester would manage a forest property, the State College of Forestry was established and put in charge of 30,000 acres of land which the State bought and turned over to Cornell University for the purpose. The university holds the title to the land for 30 years, and is expected to conduct the experiments out of the profits of the forest itself, with the help of a working capital of \$30,000, which the State provided to start with.

The college tract is typical of the Adirondack woods, being chiefly a hard wood forest, from which the white pine and, to a great degree the spruce, have been culled by lumbermen. The policy adopted is to replace the old decrepit natural forest with a new more valuable forest. It is required that this be done with the profits of the harvest of the old crop. A contract has been made under which a railroad has been built into the tract and a market is provided, both for the logs and for the cord wood, which is 3 or 4 times as great in volume as the logs. Since the conifers

are more valuable than the hard wood, the young conifers are saved in the logging, and occasionally seed trees of conifers, as well as of hard woods, are left. It seems best, however, under existing conditions, to supplement the natural supply of young growth by planting. Large nurseries have accordingly been established in which the trees are grown from the seed and transplanted to the woods when 2 or 3 years old. More than 1,000,000 seedlings are now on hand. Planting is necessary only for the conifers. A mixture of hard wood in the forest is desirable, but enough grows without assistance. (1000-1003.)

5. Forestry in Pennsylvania.—Mr. HAMILTON thinks Pennsylvania has the best forestry laws of any State in the Union. Authority has been granted to purchase lands on the headwaters of the Allegheny, Susquehanna, and Delaware rivers for the purpose of protecting the water supply of the cities situated on those rivers. The Forestry Commissioner has authority to purchase lands at tax sales, and the Forestry Commission has authority to condemn lands for forestry purposes. Some lands have been purchased outright. It is hoped that the State will soon have many thousands of acres reforested and preserved from fire. By a proper system of reforesting Pennsylvania can, in 90 years or less, pay a large part of the expenses of government from the income derived from forests, and in the meantime give profitable employment to many citizens in planting and maintaining the forests. (364.)

Mr. Hamilton says that formerly large areas of Pennsylvania hemlock timber were cut simply for the bark, and the trees left to decay or burn on the ground; but in the districts cut in recent years everything has been cleared up, the wood being used for building purposes and for paper. (364.)

6. Forestry legislation advocated.—Mr. GREELEY is deeply impressed with the importance of doing something to preserve the young second growth evergreens, and as much as possible of the evergreen forests of the Northwest. Great parks of these evergreens, particularly at the heads of great rivers and on poor nonagricultural lands, should be preserved. Thousands spent by Congress in this way would save the expenditure of millions for dikes to save the country along the Lower Mississippi. The stripping of the great evergreen forests is producing desert conditions farther east from the mountains every year. Mr. Greeley declares that the greatest thing Congress can do for the nation to-day is to set aside immense parks at the heads of all the great streams to hold the snow. (944.)

Mr. NAPPZGER proposes the transfer of the forest reservations from the Interior to the Agricultural Department, under which he thinks they would be much better patrolled and protected. (966.)

VIII. IRRIGATION.

A. Its extent and importance.—1. **Early history of irrigation in America.**—Mr. MEAD, expert in charge of irrigation investigations for the Department of Agriculture, says irrigation is far from being a recent development in the United States:

"In many parts of the Southwest, notably in northern New Mexico and Arizona, there are well-defined remains of irrigation works which have outlived by many centuries the civilization to which they belonged. Near Las Cruces, N. Mex., is an irrigation ditch which has an unbroken record of over 800 years of service. The Spanish settlers along the Rio Grande were irrigating their gardens 70 years before the settlement of Jamestown. It is true, however, that irrigation by English-speaking people is only about 50 years old. For its beginnings we must go to Utah where the little band of Mormon emigrants were compelled to adopt it to save themselves from starvation. It was 20 years after the beginnings in Utah that irrigation came to be an important factor in the growth and settlement of Colorado and California. It is an interesting fact that the earlier attempts in these two States where irrigation has assumed the greatest importance were made at the same time. The discovery of gold in California created the overland trail and opened the great interior valleys of the arid West to miners and stock raisers. At the stage stations, bordering on streams and in the vicinity of mining camps, men without any knowledge or experience built small, rude ditches and turned water on the thirsty soil. In every instance work was begun without apparent consideration of future necessities, and by men to whom the whole subject was strange and new. It is only by understanding this lack of direction and the haphazard methods which prevailed in the beginnings of our age that we can understand the present situation." (1060.)

Colorado was the first of the arid States to assume public control over the diversion of water from streams. In providing for this control it was necessary to know the capacities of the different ditches in use. Mr. Mead was employed during 2 summer vacations by the State engineer to make official measurements of the capacities of the irrigation ditches of the State having adjudicated rights to water. These were the first of such measurements made. After 2 years of this vacation employment Mr. Mead resigned his professorship in the State Agricultural College to become assistant State engineer, but returned to the college in 1886, when a school of irrigation was created, as professor of irrigation engineering. This was the first professorship of that branch of engineering in the country. (1049.)

2. Necessity of irrigation in the West.—Mr. MEAD says:

"There are few countries in which irrigation is destined to assume greater importance than in the United States. Throughout nearly all that portion of the country west of the one hundredth meridian successful agriculture is not possible without it, while each year sees an increase in its use east of that meridian. Leaving out of consideration Alaska and the recently acquired insular possessions, in some of which irrigation is already an important factor, the area of the United States east of the one hundredth meridian is 1,948,830 square miles. West of that meridian there are 1,443,849 square miles. Taking this meridian as an approximate division of the humid and arid portions of the United States, they stand in a ratio of about 53 to 47. The humid portion is, however, somewhat larger than this. There is a narrow strip of well-watered territory along a part of the Pacific coast, and scattered throughout the arid region there are relatively small areas with a rainfall considerably above that of the surrounding country, and where crops can be grown without irrigation. Making the one hundredth meridian the eastern boundary of the arid region is also purely arbitrary. The decrease in moisture begins 500 miles east of the Rocky Mountains, and gradually but irregularly increases as they are approached. Taking into consideration these minor modifications of the rough division changes the percentage of humid to arid land to a ratio of about 60 to 40.

"Within the limits of the arid region it is not too much to say that irrigation is the basis of civilized life. In many of the arid States the value of the crops grown by irrigation exceeds the output of the mine or the profits of the factory.

"By providing an abundant food supply, moreover, irrigation has made possible the operation of many mines and the development of important industries. Irrigation has also beautified the landscapes of the water areas, lessening the dust and discomfort, and rendered life more healthful and more attractive. The oases of fruit and foliage and the marvelous beauty of the gardens and orchards of southern California have done as much to fill the transcontinental trains from the East with health and pleasure seekers as has the healthful and enjoyable climate of that region. * * * The cities of Phoenix, Reno, Boise, Salt Lake, and Denver are almost as much the creation of irrigation as the farms and orchards which surround them." (1060.)

3. Area irrigated.—Mr. MEAD says that in every State, including even California, the leading irrigated State of the country, the irrigated area is a very small proportion of the total. (1069.)

Mr. WHITNEY says the public lands of the arid States amount to 560,000,000 acres. Only 3,600,000 acres in these States were irrigated in 1899, and according to the estimates of the Geological Survey, only 74,000,000 acres are capable of being irrigated. Many areas have been abandoned after being settled because of the extreme scarcity of water. (862.)

4. The semiarid region.—Mr. MEAD says there is a very large district, embracing the western portion of Texas, Kansas, Nebraska, and the Dakotas, which was first settled in the humid parts, but is settled sufficiently in the western or semiarid parts to render irrigation problems important. This is in some respects among the best parts of the arid region, because the ditches can be built at small cost, the country being well adapted to the distribution of water, and a comparatively small amount is required to supplement the rainfall. Farther west, with only 10 inches of rainfall, more moisture must be supplied by irrigation than where there are 20 inches of rainfall and less evaporation.

Mr. Mead submits the following problems affecting this central region: In the Dakotas it is very expensive to bring water from the Missouri River. In Nebraska there is uncertainty at present regarding the State law; but as the North Platte can not be utilized to any great extent in the West, and the Loupe is a good stream, Nebraska has in these two rivers an opportunity for very large development. In Kansas the question is as to the extent of the underflow, and whether it is practicable to pump it up. In Texas, and also through Arizona and New Mexico, there is a considerable territory irrigable from springs and wells. (1070.)

Mr. WHITNEY, Chief of the Bureau of Soils in the United States Department of Agriculture, says the semiarid region of the country extends generally from the one hundredth meridian to the foot of the Rocky Mountains. It has from 15 to 20 inches of rainfall yearly, but so distributed that only occasionally are the conditions favorable for crops. In favorable seasons the crops are good, but in 3 years out of 5 there are disastrous droughts, and the profits of the 2 successful years are used up. With 20 inches of rainfall, about half the rainfall of the East, provided it is fairly well distributed, good crops can be grown in the semiarid regions, but the uncertainty and unequal distribution of the rainfall has caused the abandonment of many farms. With less than 15 inches of rainfall lands are seldom or never successfully cultivated except in certain areas in Washington and California. Mr. Whitney says the problem of the semiarid regions is perhaps one of the most serious problems in the agriculture of this country. In the far West aridity can be overcome where irrigation is practicable, but so far as known there is no bright future for irrigation in most of the semiarid region. In 1889 there were only 20,000 acres of land under irrigation in Kansas, and only 67,000 acres under irrigation in North and South Dakota, Nebraska, Kansas, and Texas; and the possibilities of getting water are small in comparison with the areas which need to be watered. (861.)

5. Irrigation in the East and South.—Mr. MEAD says that while irrigation will never have the importance in the East that it has in the West, there is every reason to believe that it will be largely employed throughout the humid regions in the growing of

high priced and special products. Work done in Connecticut, Massachusetts, and New Jersey shows that in the growing of small fruits irrigation is exceedingly profitable, and it is already being largely utilized in market gardening. The cranberry growers of Wisconsin and farmers in the sandy pine lands of the Northwest are beginning to irrigate in order to get crops started and a sod established. The tobacco growers of Connecticut use irrigation to some extent in growing fancy varieties. In the South irrigation seems certain to have a very large usefulness. Within 5 years more land has been brought under irrigation in southern Louisiana and southern Texas than in any single State of the arid region during the same period. Irrigation in these States is quite different, from an engineering standpoint, from that of the arid regions, where there is a rapid flow away from the mountains and the water is conducted by gravity. In the South the streams are practically stationary. The canals are simply banked reservoirs; instead of cutting below the surface of the ground two banks are built, sometimes 200 feet apart, and the width of the canal has nothing to do with the cost of construction. The water is then pumped up from the river into the canal and the current is caused by turning water out at different points rather than by the inclination of the land. This method of irrigation is being extended throughout an area about 200 miles long and 50 miles wide.

The first canals were taken out of sluggish streams flowing into the Gulf, but when the value of the rice product became established and land rose in value from \$5 to \$50 and \$100 an acre, it was seen that those streams would not supply the need, and the pumping stations are now being supplemented largely by wells, hundreds of which are going down in Louisiana. A study is being made to determine the source of that water supply; if it is reinforced from the Mississippi, irrigation from wells can be indefinitely extended. (1069.)

Mr. Mead predicts that the South is also likely to develop irrigation in the growing of forage crops, wherever water can be obtained at sufficiently low cost. Alfalfa, for example, which in the middle East freezes out in the winter, will live through the winter and become a perennial in Louisiana. (1070.)

Mr. Mead says the economic and legal phases of irrigation have already ceased to be sectional questions. Where development has gone far enough in the East the same questions arise as in the West. In the South, also, the question has come up as to who has the better right to the water where the supply is not equal to the demand, and some system of priorities will have to be established there. On one of the streams last year so much water was pumped out that the river changed its direction and ran up stream for 50 miles, and salt water came in from the Gulf and rendered useless the pumps farthest downstream. In like manner, if there should be in the East any considerable demand on the streams the right to take water will be called in question. (1070.)

6. Possibilities of irrigation.—Mr. Powers thinks the nation has not begun to wake up to the possibilities lying before the country as the result of irrigation. The development of irrigation, however, will have to wait for transportation and markets. If the Western States can develop a market for fruits or anything which will bear transportation to the East, there will be successful farming on a large scale. Mr. Powers believes that this market will be developed within the next 25 or 30 years. (182.)

Mr. MEAD remarks that probably not more than 10 per cent of all the lands of the arid region can be irrigated, while of the arid lands still remaining public the irrigable portion is certainly not over 5 and probably not over 2 per cent, the easily irrigated lands having passed into private hands. The public lands along many rivers require more water than the streams contain. But a small fraction of the Columbia River can be used, not all of the Colorado can be utilized, and it is doubtful if the Missouri can ever be completely used. (1063, 1066.)

Mr. WHITNEY says that, unfortunately, nearly all of the water in California, Washington, and certain parts of Arizona and New Mexico has already been appropriated and is now used to its fullest extent, except such as may be added by the construction of reservoirs for the storage of waste waters. There are areas in Montana, Idaho, and Wyoming, however, where there is still some available water. It is estimated that about 74,000,000 acres can be irrigated by the construction of reservoirs. The possibilities of irrigated soil are very great for special crops, especially fruit crops and alfalfa, but it no longer pays to irrigate wheat. (878.)

California.—Mr. NAFZGER believes that large portions of the arid lands of California, but never even approximately all of it, can be irrigated by extensive dams and reservoirs. (951.)

B. Water rights.—1. *Necessity for legislation.*—Mr. MEAD emphasizes the necessity of laws for the regulation and control of streams:

"It is just as necessary for the farmer to know who owns the water he uses as it is for him to know that he has title to the land that he cultivates. In the arid region of the United States the character

of titles to water has an especial importance, because of the scarcity of the supply. With very few exceptions, there is more irrigable land along the river than the stream will serve. Hence, whoever controls the stream practically controls the land on which it is used, because he can dictate what land shall be made productive and what lands must remain forever arid and almost worthless." (1061.)

The importance of adequate water laws, Mr. Mead goes on to say, was not at first appreciated. The settlers in Utah had to build and operate ditches to keep from starvation, and it was some years before they began to study water rights. There was no need of legislation, because the people were all practically of one faith, and their religious advisers were also their directors in temporal affairs, including the settlement of quarrels over water, but in recent years litigation has been a conspicuous feature of irrigation development in Utah, and there is great need of a good code of water laws. In California millions of dollars had been invested in canals before the controversy arose over riparian rights. Another reason assigned for the neglect of this legislation is that many of the States interested in irrigation lay partly within the humid region, and the humid portions having been first settled, the importance of irrigation was not realized by the first inhabitants, who framed the earlier laws. Even the irrigators did not for a long time realize the difference between the institutions of arid and humid lands, the prevailing idea in the early settlements being that they were to create communities the counterparts of those they had left in the East, and the early settlers, as a rule, opposed any legislation which would restrict or define their rights or make rivers public property and provide for their systematic disposal, as is done with public land. It was not until the growing scarcity of water began to rob some of the lower ditches that any headway could be made in legislation, but as ditches multiplied it was seen that when the demand for water was greater than the supply, those at the head of the stream could take all the water, "while those lower down, unless protected by law, must see their fields parch and their crops wither whenever the stream ran low." The ditches of the Greeley colony, for instance, were on the lower end of the stream, and they were robbed by ditches built later farther upstream. (1052.)

In many of the States and Territories there is no orderly procedure for the settlement of water rights. Controversies are sure to arise in such cases between the owners of the ditches along the stream, and where the irrigators are lawless the dams and head gates are often torn out. The courts have authority to adjudicate the rights, but the litigation is very costly and never finally settles anything. In a California case, which Mr. Mead regards as typical, "A" brought suit against "B," and was decreed to have the first right to the water of a stream, and "B" was enjoined from interfering with "A's" use. "B" then brought suit against "C" and "C" was enjoined from interfering with "B's" use. "C" thereupon instituted a suit against "A," and the latter, relying upon the fact that there had been two judgments in his favor already, put up a weak defense, and "C" was decreed to have a superior right to "A." Mr. Mead thinks that some orderly tribunal should have been provided at the outset to manage and dispose of the water of the streams as the Government has disposed of the public lands. If that had been done, records of claims and appropriations would have been complete and accurate, and the danger of excessive and speculative appropriations would have been averted. (1053, 1054.)

In recent years litigation over water rights has been a conspicuous and injurious feature of irrigated agriculture. Mr. Mead attributes this to two causes, the first of which is the lack of any plan for the establishment or protection of rights to streams. Farmers will resort to almost any expedient to obtain the water they believe belongs to them. The remedy for this evil is to have water divided under public control. Where this has been done, controversies are far less numerous than in other States. The second reason for controversies has grown out of the mistakes made in the adjudication of water rights. Before the value of water was appreciated titles to its use, in amounts far beyond the possible needs of appropriators or the capacities of the streams or canals, were repeatedly established. When these decrees were rendered, the majority of appropriators believed that rights for irrigation were limited to the lands already irrigated, and that the actual volume stated in the decree was unimportant. Recent decisions, however, have recognized the right of the holders of these decreed appropriations to sell the entire volume granted. Every attempt to do so is contested. Irrigators have in practice built up a system on one theory of water rights, while the courts have rendered a number of decisions based on another theory. If the doctrine laid down in these decisions is carried to its logical conclusion, it will transfer the ownership of a majority of the streams of northern Colorado to a few early appropriators, and compel a large proportion of the users of water to purchase what they have heretofore had for nothing. Irrigation practice in that State, Mr. Mead thinks, is superior to irrigation law. He quotes from a brief of Judge Victor A. Elliott, of Colorado, forcibly stating the evils which have been

created by this situation, and adds that the settlement of the issue is of very great importance to the entire nation. There is need of more general agreement regarding the nature of a water right and more effective means of disposing of streams. (1058-1060.)

Mr. WHITNEY calls attention to the necessity for uniform State laws on the subject of irrigation, and adds that certain phases of the subject will undoubtedly have to be taken up by the National Congress, especially where interstate streams are concerned. (880.)

2. The nature of water rights.—Mr. MEAD says that each State and Territory of the arid regions has some legislation governing the use of water in irrigation. The General Government, in 1866, passed a law recognizing local laws and customs relating to mining and irrigation, and since that time has not interfered with whatever system the States and Territories have seen fit to adopt. The laws of the States and Territories, and the decisions under them, have apparently settled certain issues: (1) The first appropriator from a stream has the first right to its water, and the rights of subsequent appropriators follow in order. (2) All rights must be based on the actual beneficial use of the water.

Concerning the limitations of an appropriation, however, there is wide difference of opinion and of law. In some States and Territories water is regarded as personal property, the owner of which can lend or sell it like any other commodity, the appropriation not being attached to any particular tract of land nor to the ditch through which the water was first diverted. In other States, water rights are attached to the land and the appropriations limited to the necessities of the land. The conflicting views regarding the nature of a water right are largely due to the different methods employed in constructing ditches. Where ditches are small and the same person owns the land and the ditch, the tendency is to favor the union of land and water, but on many streams corporations have built costly works in advance of settlement to supply lands they never expected to own. Under such conditions, the tendency has been in favor of making the owners of the works the appropriators of the stream, and giving them the greatest possible freedom in disposing of the water supply to users.

"Another troublesome problem in many of the Western States has grown out of the conflict between the rights of appropriators of water under State laws and the rights of riparian proprietors, as recognized by State constitutions. In Colorado, Wyoming, Montana, Idaho, Utah, Nevada, and in the Territories of New Mexico and Arizona, riparian rights have been abrogated, but in California, Washington, Oregon, the two Dakotas, and Nebraska the constitution recognizes the common-law doctrine of riparian rights, which requires that streams must flow undiminished in volume. Later on these States have passed laws which permit irrigators to appropriate and divert the entire supply until it is an open question which of these two conflicting policies is to prevail. It will hardly be wise for either the State or General Government to extend any considerable aid, while whatever is done by private enterprise will be attended by so much hazard as to make development comparatively slow and uncertain." (1062, 1063.)

Mr. Mead says many canals and ditches carry volumes of water sufficient to irrigate from 100 to 500 farms. The limitations of the water rights of the canal owner are fixed by law; the owners of farms along such canals purchase from the canal owners the right to the use of water, also called a water right, the limitations of which are fixed by the terms of the contract. The right of the canal owner gives him a continuous flow of the water appropriated with the right to dispose of it to whomsoever he pleases, and with no restrictions as to the means of diversion or place of use. The water-right contract gives the irrigator the right to water only during the irrigation season; not a continuous flow, but one varying with his necessities. These contracts fix the conditions of the traffic in water, the conditions on which the users receive it, and its value. Some of the contracts provide a charge for the right to the water itself, and also a charge for the service rendered in the delivery of the water, while some of them are of a character that contemplates the eventual transfer of the works and the appropriation to the users of the water. (1054.)

Mr. Mead submits specimens of water-right contracts used in some of the Western States. (1071-1074.)

3. Provisions of statute law.—*Colorado.*—Mr. MEAD says that Colorado passed the first law providing a method for establishing water rights. This law gives to each claimant the right to inaugurate in court a procedure under which all claimants to the same water supply can be compelled to come into court and have their relative priorities and amounts adjudicated. It provides that the streams shall be under public control, and the State Water Commissioner shall in times of scarcity divide the water among the holders of adjudicated rights. (1053.)

Kansas.—Mr. MEAD says that in Kansas the statute recognizes the doctrine of riparian rights east of the ninety-seventh meridian, and the doctrine of appropriation west of it. Mr. Mead deems this a sensible arrangement, although it sounds arbitrary. (1053.)

Nebraska.—Mr. MEAD calls attention to the very rapid growth of Nebraska in recent years. Many large canals have been built, and a large amount of land in the western part of the State brought under cultivation. This development he attributes in part to favorable natural conditions, but more to a very excellent law providing for the systematic record of water appropriators' rights and their legal recognition. All this, he adds, has been changed by a recent decision of the supreme court, declaring the common-law doctrine of riparian rights to be the law in that State. If this is the case, every diversion of water is illegal. No one knows what is to be the result. Irrigators and investors in canals are alarmed, and the millers of Nebraska, at a recent meeting, perfected an organization under which they are to institute lawsuits to enforce the decision of the court and close up the irrigating canals that are depleting streams. (1053.)

California.—Mr. NARTZGER testifies that irrigation in California is in the hands of private corporations and individuals, who obtain their right to the water chiefly by appropriation. Under the general riparian law, the individual who finds a water source or a stream, who has lands upon which he can take it for irrigation, appropriates as much as he may think he requires, and if he proceeds to distribute it and use it will hold so much as he uses against adverse claimants. Water developed by artesian wells is sometimes sold to individuals and becomes an easement upon the land. (953.)

Wyoming and Canada.—Mr. MEAD states that in Wyoming the waters of streams are public property and are managed by a special tribunal, from which every intending user of water must secure a permit. Where all the water has been previously appropriated permits are refused. Under this law, which has been in force for 10 years, the rights of over 4,000 appropriators have been established without litigation or controversy. (1054.)

Canada has been dealing with the problem of water rights for several years, under conditions similar to ours, and Mr. Mead deems the result worthy of study. He compares the general principles underlying the Canadian irrigation code with those underlying the irrigation code of Wyoming, which has gone farther than any other of the arid States of this country in the direction of the public control of streams:

CANADA.

- (1) That the water in all streams, lakes, ponds, springs, or other sources is the property of the Crown.
- (2) That this water may be obtained by companies or individuals for certain described uses upon compliance with the provisions of the law.
- (3) That the uses for which water may be so acquired are "domestic," "irrigation," and "other" purposes, domestic purposes being limited to household and sanitary purposes, the watering of stock, and operation of railways and factories by steam, but not the sale or barter of water for such purposes.
- (4) That the company or individual acquiring water for irrigation or other purposes shall be given a clear and indisputable title to such water.
- (5) That holders of water rights shall have the protection and assistance of permanent government officials in the exercise of such rights.
- (6) That disputes or complaints regarding the diversion or use of water shall be referred to and settled by the officials of the government department charged with the administration of the act, and that decisions so given shall be final and without appeal.

WYOMING.

- (1) That water is not subject to private ownership, but is the property of the State.
- (2) That the board of control is the trustee for the administering of a great public trust in the interests of the people of the State.
- (3) That all rights to divert water from the streams must be based on beneficial use, and that the right terminates when the use ceases.
- (4) That the volume diverted shall in all cases be limited to the least amount actually necessary for the accomplishment of the purposes of the diversion.
- (5) That under no circumstances shall the water diverted for irrigation exceed 1 cubic foot per second for each 70 acres of land actually irrigated.
- (6) That the right to the use of the public waters attaches only to the use for which the right was originally obtained.
- (7) That the right of diversion for irrigation attaches to the land reclaimed and none other; that the transfer of the land carries with it the right, and that apart from the land the right can not be transferred.
- (8) That when a ditch waters land not the property of the ditch owner the right attaches to the land on which the water is used and not to the ditch. The owner of the lands irrigated makes the proof of appropriation and the certificate is issued to him. No certificate of appropriation can be issued to a ditch owner for the watering of lands not his own. The ditch owner is a common carrier and is subject to regulation as such.
- (9) That when proper diligence has been exercised in the construction of works and in applying the water to the purpose for which it is diverted the priority is fixed by the date of beginning the survey. When diligence is lacking, the priority dates from the time of use. (1060, 1061.)

4. Interstate complications.—Mr. MEAD refers to conflicts which have arisen between States as to their rights in interstate streams, and illustrates the nature of some of the interstate complications growing out of irrigation by means of a map of the Bear

River, which rises in Utah, flows into Wyoming, crosses back into Utah and again into Wyoming, whence it enters Idaho, and finally returns to the State of its origin. The stream is thus cut into 5 sections. Ditches are taken out of the stream along its entire course, and the people of Wyoming, though complying with all the requirements of the State law, can not enforce the doctrine of priority, because some of the last ditches built have their head gates just over the border in Utah. It is useless to attempt to enforce priorities on the upper section of the stream in Wyoming, even in favor of earlier rights on the lower section in the same State, because if the water were not taken out above it would go into Utah and be taken there. Mr. Mead adds that the same thing is true in the case of Bear Lake. Irrigators on the lower end of the river desired to develop an important storage basin, but were confronted by the fact that all the ditches in Idaho would have the first chance to utilize the water supply.

Mr. Mead goes on to say that if the development of irrigation could have been foreseen these complications could have been avoided by a change of about 10 miles in the boundary line between Wyoming and Utah, and that in a great many cases a very slight change of State boundaries so as to follow divides would have entirely obviated interstate problems which are now unsolved, and must be settled either in the courts or by legislation. (1064, 1067.)

5. Conflicting rights of irrigation and navigation.—Mr. MEAD says the General Government looks after the rights of navigation, and the States after the interests of the irrigators. The relative rights of navigation and irrigation were raised in litigation over the waters of the Rio Grande, and the decision of the United States Supreme Court indicated a strong tendency toward maintaining the interests of navigation. The same questions may arise along the Missouri River and its tributaries. If it should become necessary to close the head gates of the irrigating canals to prevent steamboats from running aground, it would prevent any considerable increase in the acreage now cultivated. Mr. Mead believes, however, that as the tendency of irrigation is to equalize the discharge of streams, reducing the floods and raising the low-water discharge, its extension on the headwaters of the Missouri will be a help instead of an injury to navigation. (1064.)

C. Engineering methods and difficulties.—**1. Irrigation by wells.**—*South Dakota.*—Mr. GREELEY says much of the drier part of South Dakota is underlaid with water, which, when reached by artesian wells, comes to the surface with great force and in enormous quantities. In some sections large open basins have been dammed up and lakes made from great wells. In some instances trees have been planted around the lakes and fish put in and beautiful spots made with surprisingly little cost. The effect of the water is seen, when the hot south wind is blowing, in a flat-iron-shaped piece of green stretching away to the northeast. (933.)

California.—Mr. NAFZGER testifies that there are some quite extensive belts in California, where there are flowing wells of large extent. There is also a vast amount of pumping done where the water will not rise to the surface. Artesian water is seldom salty or strongly impregnated with alkali, though surface waters frequently are. The artesian waters are usually suitable for all crops, as well as for domestic purposes. (953.)

Louisiana and Texas.—Dr. STUBBS says a bed of gravel nearly a hundred feet thick was discovered by the geological survey of Louisiana, in 1898 or 1899, underlying the rice district, and since then from 300 to 500 wells have been bored. The water comes within a few feet of the surface, and the fields are irrigated with small pumps without difficulty. The wells are being bored (January, 1901), at the rate of 10 to 20 a day. Dr. Stubbs says he can give no conception of the wonderful activity being displayed in the rice fields. This same condition runs into Texas as far as Houston. (773.)

2. Storage reservoirs.—Mr. MEAD says a great many torrents carry an immense flow of water at first and then run down to nothing. These streams must be stored in order to utilize their waters, and the problem of storage is complicated, involving, in the Southern streams, the problem of sediment. It is disastrous to build a reservoir in the channel of a river and then have it fill up and necessitate the moving away of the settlers. The Department of Agriculture is studying this question, and has arranged with the Agricultural College of Texas to gather samples from the streams to ascertain the probable result of depositing the mud they carry upon the soil. (1070.)

Mr. Mead says that, with the exception of two or three reservoirs in Colorado, all the reservoirs in the West are private property. So long as there is water running in a river which can be diverted there is no need of reservoirs, consequently they receive little attention until the natural flow has been utilized. On the Poudre River, in Colorado, storage has probably been carried farther than any other place in the whole Rocky Mountain drainage area. The highest water occurs in May, and

from the middle of that month to the middle of June nearly half of the entire year's discharge runs away. The farmers grow crops which require more water in July, August, and September than the stream will supply, and it has thus become necessary to build reservoirs to hold back the surplus flow of the early summer until it is needed. Natural depressions lying outside of the channel of the stream have been utilized for this purpose. The development of this reservoir system has given rise to a very interesting system of exchanges between the canals. (1061.)

Mr. Mead says that where reservoirs are located outside of the channel of the stream there is no question of public policy involved in their construction and operation as private works, but where they are located in the channels of running streams, and especially in the mountains on the headwaters of streams, it is a question whether they should not be built as public works, even if private capital is willing to undertake their construction. The water from reservoirs so located has to be turned into the natural channel of the stream, and if there is no public control of the streams irrigators will not discriminate between the natural flow and the stored supply. If public regulation is attempted perplexing questions are sure to arise; if the reservoirs at the heads of the streams are built and operated as public works and the water used to make more secure the supply of the appropriators of the natural flow, all these troublesome questions will be avoided. (1061, 1062.)

3. *Methods of distributing water.*—Mr. MEAD says that from the eastern base of the Rocky Mountains for nearly 500 miles the country has a slope of from 25 feet to 4 or 5 feet to the mile. Bear River in Utah, for a mile below the head of the Bear River Canal, has a fall of 120 feet, while the canal in that distance has a fall of 4 feet, leaving it 116 feet above the stream, a sufficient elevation to permit of the watering of the plateau, embracing nearly 100,000 acres of land. The Poudre River in Colorado (of which a map is shown) has a fall of 25 feet to the mile, while each canal has a fall of about 2 feet to the mile, a gain of 20 feet or more in elevation for each mile. (1054, 1055.)

Mr. Mead says that where crops are cultivated water is run down furrows, and furrow irrigation is generally employed in the irrigation of orchards. Small grain and hay are usually irrigated by flooding. (1055.)

4. *Loss of water by seepage, etc.*—Mr. MEAD says that throughout the West, except in southern California, irrigation ditches and canals are unlined, the soil being expected to retain the water in the channel; but where canals cross a stratum of coarse gravel or where there are gypsum deposits the losses from percolation are very great. In one case investigation by the Department of Agriculture showed a loss of 75 per cent of the entire water supply of a canal within less than a mile.

Quoting from a report of the irrigation investigations of the Department of Agriculture for 1899, Mr. Mead says the losses in canals from percolation, leakage of flues, evaporation, etc., are an important factor in fixing the duty of water from a river or an extensive canal system. To determine this average duty the volume should be measured at the head gate, and the duty thus determined is lower than that obtained by measurements on the laterals or at the margins of the irrigated fields, the influence of the losses on the main canal being greater than has usually been supposed. A table is submitted showing that on certain canals in Colorado, Utah, Idaho, New Mexico, and Arizona, according to measurements made at the canal head gates, 5.47 acre-feet of water were required on an average to irrigate an acre of land, or more than twice as much as where the water was measured at the place of use, showing that the losses from the canals from seepage and evaporation amounted to more than half the entire supply. This accords with many of the measurements made on irrigating canals in India and in this country. The loss of water by seepage, Mr. Mead goes on to say, is not only a very serious problem to canal owners, but is frequently the cause of grave injury to the farming lands below. The water may run into the river or cause the appearance of springs in ravines which before were dry, or it may reappear in the fields, converting them into marshes and swamps. Not infrequently thousands of acres of land have for a time been rendered valueless from this cause. The saturation of the subsoil and the gradual rise of the water level nearly always attend irrigation.

In Colorado and Wyoming, as a rule, the loss from seepage is not excessive, because the soil is of such a character as to hold water pretty well. All of the rivers that flow out on the plains, however, such as the Arkansas, the Rio Grande, the South Platte, and the North Platte, sink into the sand. The North Platte River was measured 100 miles west of the Wyoming border and found to contain 400 cubic feet per second, while a few miles east of that border it was entirely dry. (1065-1068.)

5. *Alkali.*—Mr. MEAD says that where seepage is not excessive it furnishes an inexpensive method of irrigation, but where it is excessive it may prevent the growth of

crops by the excess of water and also render the soil unproductive through the accumulation of alkali. Water passing from canals through the subsoil dissolves the soluble salts which all Western lands contain, and the subsequent evaporation of the water increases the percentage of alkali. This evil, however, like the excessive moisture, can be remedied by drainage. (1057.)

Mr. WHITNEY says the difficulties in the way of the extension of irrigation are the alkali and the silt in the water. The amount of alkali in the water is a very serious difficulty in the way of irrigation in many localities. In the Pecos Valley the alkali is so great in the lower part of the valley that the water is entirely unfit for irrigation. In the storage reservoir above Carlsbad the evaporation is so great that at the end of a long dry season the water is too salty to be applied safely to the land. Much trouble and loss have been experienced in connection with the storage of alkali water in California. The river water in Utah is very pure, because the rivers are short and rise in the snowclad mountains; but in the Pecos Valley the water travels 200 or 300 miles from the mountains and gathers up salts as it flows. The Pecos is entirely taken up about 6 miles above Carlsbad, but 6 miles below the reservoir it has about the same flow that it has above the reservoir. Frequently in the West the water of a river is entirely used up before it reaches the mouth, going out in seepage and flowing again into the river after it has been applied to the land; and by the time it reaches the mouth of the river it is very salty. (879.)

Mr. Whitney says that when the Morimons first settled in Utah they naturally took up the richest bottom lands along the Jordan River. With the increase of population settlers moved up on the highlands, and the seepage water from the irrigating canals accumulated in the low places and washed down the salts to such an extent that the most fertile lands were rendered entirely unfit for cultivation, being wet and swampy and filled with alkali. The people are therefore abandoning the soils which were once the most productive in the State, and moving up onto the bench land. (862.)

There is an area of about 90,000 acres just west of Salt Lake City, extending over to the Great Salt Lake, that is filled with alkali which is not always apparent on the surface. Frequently the surface looks like a fertile loam, and many attempts have been made to settle the country. Irrigating canals have been constructed, town sites located, and railroads built. With the first application of water good crops have been produced; with the second application, a failure; with the third, the land has become so salty that it is abandoned as desert land. Thousands of dollars have been lost in the effort to build up agriculture in that area. The soil survey of the Department of Agriculture showed that it was perfectly feasible to reclaim these lands by drainage. The expense would be no greater than the drainage of lands in Ohio and Illinois, and the profit that would be realized from the reclamation of the 60,000 acres in that tract would amount to about \$3,000,000 in property values. But there are no drainage laws there as there are in Illinois and other States, and the reclamation is prevented by the unwillingness of people to give the right of way for drainage canals through their premises. (862, 863.)

Mr. Whitney explains that the alkali in soils is derived from the natural weathering and disintegration of the rocks. Generally speaking, it is peculiar to arid regions, though it occurs occasionally in the East. The mineral springs are due to the decomposition of the rocks. In the West the decomposing rocks accumulate in the soil and stay there. No such accumulations occur in the East, because half of the 40 inches of rainfall goes down through the ground and is carried off in the rivers. In the West, on the other hand, only about 5 per cent of the very small rainfall is carried off, and then usually over the surface of the ground. (880.)

Mr. MEAD says the total evaporation from the water surface in the West ranges from 3 to 6 inches a month. Where the waters of a river are heavily charged with alkaline salts this evaporation will so concentrate them as to make them injurious; but there are very few instances of this kind. The only case Mr. Mead knows of is the Pecos River, where he thinks the phenomenon occurred only in one season. In the part of the country where the water is stored the streams carry so little alkali that the accumulation is not great, and, the water being discharged every year, there is no continuous cumulative action; hence Mr. Mead does not consider the problem of alkali one presenting insurmountable obstacles. (1070.)

6. **Prevention of seepage.**—Mr. WHITNEY declares that something will have to be done through either State or national legislation to stop the injury from seepage waters. The farmers situated on the lower levels should have recourse to damages through civil suits, and the canal companies should either be compelled to protect their canals from seepage or pay damages. (862, 863.)

Mr. MEAD says canals can be cemented on earth, as is done in California, only where winter frosts are not severe. Dumping clay into the canal and causing it to be distributed by agitating the water has been tried with good results on some Nebraska

ditches. The waters of Salt River, Arizona, contain a cementing material which in time renders its banks almost watertight, so long as they remain undisturbed. (1056, 1057.)

Mr. WHITNEY says that in California, where the water is more valuable to the companies, it is very common to protect canals from loss by seepage by wooden troughs or pipes, or by cementing the sides and bottoms of the canals and ditches, as is frequently done in sandy areas. In many cases simply the puddling of the canal would be sufficient to prevent seepage. (864.)

Mr. Whitney says that his study of soils, alkali, and seepage waters has convinced him that it will be necessary to use greater care in the application of water, to protect the soil from the injurious effects of overirrigation and the accumulation of seepage water and alkali. He thinks it safe to say that in nearly all irrigated districts twice as much land could be irrigated with the water now used, with actual benefit to the soil, if it were intelligently applied. (880.)

7. **Silt.**—Mr. MEAD testifies that all canals taken out of rivers which carry considerable quantities of mud in high waters have to be cleaned out every year. The deposits of mud can be handled as a rule without any excessive expense, but in streams like the North and South Platte and the Arkansas the sand is quite troublesome; on the lower Rio Grande the mud is an important factor. The red rise in the Rio Grande occurs when there are heavy rains along certain portions of the river where there is a red soil, and enormous volumes of mud are washed down in the river; samples have shown as much as 17 per cent of solid matter. All the ditches have to be closed during the red rise, or they would immediately fill up.

One of the oldest ditches in the United States, if not the oldest, is at Las Cruces, N. Mex. Though it was formerly a channel cut below the surface of the ground, it is now raised 4 or 5 feet above the surface of the ground. As the mud was cleaned out each year it was thrown on the banks, and when the banks became so high as to be troublesome, the mud was allowed to fill up a foot or so in the bottom. In time the ditch was higher than the stream, and the head had to be moved further up stream; it has been moved 3 or 4 miles upstream from the original location. The level of the soil on which the water and mud have been spread has also been raised from a few inches to 2 feet. The Rio Grande at El Paso has filled up its channel until the river itself is higher than some of the streets of either El Paso or Juarez. (1058.)

Mr. WHITNEY says that in Arizona, where the waters are very heavily laden with silt, there is a very distinct type of soil, undoubtedly a sediment left by the irrigation of some prehistoric race. The amount of sediment is so great that it is very difficult to maintain the modern canals, and it is also generally believed that reservoirs will quickly fill up with silt in such districts unless special precautions are taken; how to keep them open is a problem which has not been satisfactorily solved. (879.)

8. **Lowering of water levels.**—Mr. WHITNEY says the level of the Great Salt Lake has fallen 14 feet since 1865, and in a recent soil survey of the area around Ogden, 60,000 acres, or about 10 square miles, were mapped in where the lake had receded. In some places the shore line was established 9 miles beyond its former location. There are annual and periodical fluctuations in the tide of the lake which have never been explained, but the withdrawal of water for irrigation is an important cause of the lowering of the surface. (864.)

D. Economic aspects.—1. **Cost of irrigation.**—Mr. MEAD testifies that the first ditches built are always the cheapest, because they are little ditches leading out from the most favorable bends in the streams, and such ditches cost little more than laterals from main channels. The cost of irrigation from many of the earlier ditches was not to exceed from \$2 to \$5 an acre. When larger ditches had to be built the expense for the main canal and lateral would run from \$5 to \$15 an acre; at present the cost is above that, because large rivers have to be dealt with, requiring costly head gates, and the fall is less than in the first small ditches. On a good many of the canals the estimates for water now range from \$7 to \$20 an acre, and the latter price is in many localities more than can be paid, because there must be added to the cost of the water the cost of the settler's equipment, including his house, tools, and stock, and of putting the land into condition for cultivation. In many places where there is an abundance of land it is not being developed because it would cost as much to develop it as it would to buy an improved farm in the older States in the Mississippi Valley. (1065.)

Mr. WHITNEY testifies that the average cost of placing land under irrigation, as shown by the Eleventh Census, was \$12.12 an acre, and the annual cost thereafter \$1.07 an acre. The cost of opening 74,000,000 acres, therefore, would be \$897,000,000; but as the methods heretofore used have been the simplest possible, the cost per

acre will be much greater in the new areas where the water must be stored and carried long distances. The storage of water under the most favorable conditions in Arizona is estimated to cost \$4.30 an acre-foot, and at least 5 acre-feet of water must be stored for each acre, in order to provide for seasons of low water, making the cost about \$21.50 an acre. This calculation assumes that all the land that could be watered by the average reservoir is to be actually irrigated. If only half or a quarter of that area were taken up, the cost would be twice or four times as great. The value of this land, after being put under water, would be from \$60 to \$100 per acre throughout the arid regions. (878, 879.)

2. Value of irrigated land.—Mr. MEAD says that the value of irrigated land is governed by its proximity to local markets, by the climate, and by the distance and cost of railway transportation to the great markets of the world. In southern California and around Phoenix, Ariz., where citrus fruits and other high-priced products are raised, irrigated lands having no improvements excepting the orchards planted on them, have sold as high as \$1,800 an acre. Water rentals also reach a very high figure; in some instances water rents for \$45 an inch a year, and water rights reach as high as \$1,000 an inch. In the northern part of the arid region there are cheaper water supplies and cheaper lands. (1065.)

Mr. WHITNEY testifies that irrigated lands in Utah are worth from \$60 to \$100 an acre, and set out in good varieties of fruit trees, up to \$1,000 an acre. In southern California lands are worth generally from \$50 to \$100 an acre, but many orchards are worth from \$1,000 to \$2,000 an acre. (878.)

3. Products of irrigated lands.—Mr. MEAD says that the greater part of the arid region will always be largely devoted to the raising of live stock, and to gardens to supply the local markets. The live-stock industry is largely based on the use of public and private lands as a grazing ground. The practice of open ranging during the entire year has given way to the practice of feeding in winter. This has been forced upon the cattlemen by the overstocking of the grazing lands. It is therefore necessary to depend upon the irrigated lands, and the needs of the live-stock business have been one of the great incentives to irrigation, furnishing one of the best markets for crops, especially hay and alfalfa, the two leading general products of the grazing region. Mr. Mead does not think corn can ever become a general crop under irrigation, because the nights in a considerable part of the arid region are too cold for it; though it is grown in restricted areas as a part of the system of rotation. Moreover, alfalfa is a better stock food than corn. Mr. Mead also predicts that there will be no large development of wheat growing in the irrigated regions, unless there shall be a market which can be reached by water, without excessive railroad charges. The great bulk of the wheat grown now is consumed at home, and in many of the arid States not nearly enough is raised to supply the home demand. Montana, Wyoming, and Idaho all import flour and oats. The growth of the home demand for food in the mining States is more rapid than the extension of irrigation. (1065, 1066.)

Mr. POWERS says irrigation on a small scale is now found in the mountainous regions of Montana and Colorado. A ready market for a small amount of produce is found among the mine workers, etc., in those States. The products are sold at a price equal to their price in Minnesota, Kansas, or Nebraska, plus the cost of transporting them to these mining centers, and there is a profit in their cultivation. (182.)

Mr. NAPPZGER testifies that for the growing of citrus fruits irrigation is absolutely indispensable, and that the water is the chief element of cost, the land being of small value without it. (953.)

E. Irrigation by public and by private works.—**1. Governmental irrigation abroad.**—Mr. MEAD shows that irrigation in the United States differs from that of nearly all other irrigated countries. In Italy, France, Egypt, India, and Australia many of the important irrigation works are public works. In the United States every canal in operation and nearly every reservoir used in irrigation has been constructed by private enterprise. Investments of \$200,000,000 or more have been made from private funds to provide water for the lands of the arid West. Colorado, however, has, with State funds, built two or three reservoirs and begun one canal. (1050, 1051.)

2. Results of individual initiative.—Owing to the fact that irrigation works have been left to private enterprise, Mr. Mead says, there has been a delay in the enactment of laws for protecting irrigation investments and securing to the user of water his proper share of the stream on which he lives. Where canals are built with public funds, laws governing the division of streams receive early attention, and the leading consideration in the location of the works is the conservation of the water and its use on the best land. In the United States, on the other hand, public considerations have received but little attention in the location of works, or in the

enactment of laws determining rights to streams. The places where ditches could be built at the least cost were first selected, and where these locations have been utilized larger works have been undertaken. After the natural flow of streams has been absorbed, reservoirs have been constructed to store the flood waters and the waters which would otherwise run to waste. Irrigation has developed most rapidly in States having a favorable climate, like California, or people of exceptional enterprise, like Colorado, or where the proximity of mines has led to a large local demand for farm products; thus, Utah has more cultivated land than Montana, although the area susceptible of irrigation is many times greater in Montana than Utah.

Irrigating canals being private works, the leading consideration has been the cheapness with which they could be built and the profit with which water rights could be disposed of, instead of being the abundance of water supply. Hence there are many streams in the West where the natural flow has been already fully utilized. On hundreds of streams the capacity of the canals and ditches is fully equal to the water supply, and in some cases, as in that of the Arkansas River in Colorado and Kansas, there are more ditches than can be filled, covering more land than the stream can be made to irrigate, so that the people dependent upon them suffer from drouth as severely as those who depend on rain.

As a rule all the land which can be irrigated cheaply is now being irrigated, or is owned by parties who intend to irrigate, and the streams which can be easily diverted will require reservoirs to make a further extension of the cultivated area safe and profitable. Yet there is a great field for future development. The large rivers, like the Missouri, Big Horn, Snake, Rio Grande, Green, and Sacramento, are as yet almost undiminished in flow. The cost of works to utilize them has been too great, and in many cases will, for years to come, be beyond the reach for private enterprise. This is one reason why State or national aid is regarded as a necessity, or at least a wise public policy. (1061.)

3. The argument for public irrigation works.—Mr. MEAD says there will have to be an expenditure of public funds to secure certain developments. He does not believe that it will pay private capital for some time to take water from rivers like the Missouri, because the land would not pay the cost. The value of irrigated lands and of irrigation improvements is measured by the value of lands in the Mississippi Valley, or of lands irrigated by public works. There are projects, however, that would perhaps pay as public works, because in bringing land now entirely worthless into cultivation homes and taxable values are created. This, Mr. Mead says, is the argument for State or national aid. (1067.)

4. Desirability of public reservoirs and artificial lakes.—Mr. MEAD is confident that the subject of reservoirs will soon assume a much greater importance than in the past, because on many streams it is the only means by which the irrigated area can be extended. It can not be too soon determined, therefore, whether they are to be constructed as private or public works. Mr. Mead believes that reservoirs located away from the channels of streams can be safely left to private enterprise, but that those built to supplement the natural flow of streams and to meet the needs of a number of ditches or canals should be public works, either State or National, depending upon whether or not all the water rights continue to be regulated by State laws; in that case the reservoirs should be owned and operated as a part of the State system. Any uncertainty regarding future legislation is likely to interfere with the building of ditches and the reclamation of new lands.

Mr. Mead goes on to say that this subject is of paramount importance in each of the arid States, and that the local conditions being understood by the people who have made the beginning makes it possible for the States to bring to the solution of irrigation problems a higher intelligence and more direct interest than can be secured in any other way; and he attributes their lack of success in the past in part to failure to appreciate the necessity for legislation, and to disagreement regarding the principles which should govern the ownership of water. The States are entirely capable, in Mr. Mead's judgment, of regulating and protecting all interests concerned, but they are not capable, under present conditions, of securing the full utilization of their resources. The building of reservoirs as public works does not appeal to private investors. The public receives benefits from irrigation works which private capital can not share. Such works give a high value to land now worthless, and greatly increase the taxable resources of the States and the productive wealth of the country. Unfortunately, the arid States lack the resources for undertaking the construction of canals and reservoirs. They are sparsely populated, and the heavy expense of maintaining local government has to be paid for by taxes levied on only a small fraction of the land. The public land contributes nothing in taxes, and can not be used as a basis of credit in borrowing money for its improvement. (1062, 1063.)

Mr. GREELEY, secretary of the Board of Regents of education of South Dakota,

COXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

declares that if the Government would use the artesian supplies of water to make great lakes and streams where they are needed, distributing the lakes throughout western Nebraska, southwestern Dakota, and other places where the hot winds pass over the prairies, it would make a lovely, habitable, and healthful region, where now at times there is almost a desert. Many hundreds of thousands of dollars expended in river improvements might well be diverted to this use; one-half the money put into the improvement of the Missouri River would make a great many lakes, stocked with fish and surrounded by trees. There are also other large appropriations which might be diverted to this purpose. (933.)

5. Possibility of conflict with existing rights.—Mr. MEAD says there is considerable discussion in the West about the best means of extending Government aid. Communities have built up their systems under local laws and customs and do not want them interfered with; on the other hand, another element is in favor of a complete national system of laws and administration. (1067.)

Mr. NAPTZEGER, of California, does not think any general plan of irrigation inaugurated by the Government would conflict with existing riparian rights, because the Government's undertakings would probably be reservoirs in undeveloped sections, as most of the streams that could be used by individuals or private corporations are already appropriated. (953.)

6. National aid through modifications of the land laws.—Mr. MEAD says the present land laws were framed for the humid region, and do not meet the requirements of the arid region. He illustrates the benefits which might result from their modification by reference to the so-called Carey act, which gave to each arid-land State the control of 1,000,000 acres of land during its reclamation. This has resulted in Wyoming in the irrigation of about 100,000 acres of land which would never have been reclaimed under the public-land act. In Idaho the projects inaugurated under the Carey act embrace about 400,000 acres. In both States the condition of irrigators is superior to the average result where land is reclaimed under the homestead or desert-land acts. Actual settlement and cultivation of land are required by the act, and no one can acquire more than 160 acres, attached to which is a water right and a share in the canal. Colorado also received 500,000 acres of public land to provide a fund for making public improvements, some of which has been spent on irrigation works, but the greater part of which has been expended in building roads and bridges. Utah was recently given 500,000 acres of land to provide a reservoir fund. (1064.)

Mr. Mead says that a number of bills have been introduced in Congress embodying the idea that the States be given the proceeds of the sales of public lands within their borders as a fund with which to construct public irrigation works. During the year 1900, 14 western States would have realized \$2,107,000 from the net receipts of such lands. These revenues, Mr. Mead says, can be largely increased by collecting rentals or other revenue from the public grazing lands. (1063.)

7. Objections to Government aid.—Mr. MEAD says there has been in the East a feeling that any large development of agricultural lands would interfere with the prosperity of Eastern farmers; and there has been a question as to the constitutionality of irrigation by the General Government. Mr. Mead says, however, that there can be legislation which will very materially promote successful development without any appropriation of money. (1066.)

Mr. BRIGHAM believes that nearly all farmers east of the Mississippi are opposed to the plan of a national appropriation to survey the headwaters of the Missouri and other great Western rivers with a view to impounding their water for irrigation. This survey would be but the opening wedge for a demand that the Government erect dams and reservoirs and invest hundreds of millions. Land capable of irrigation from such reservoirs would be obtained by syndicates and capitalists and the actual farmers would receive little benefit. The time may come when this land will be really needed, but the Government should wait till then before investing any money. (28.)

Mr. JONES, master of the National Grange, also deprecates such Government aid, as unfairly assisting the competitors of the Eastern farmers. He says the Eastern Senators who opposed Government aid to irrigation had the sympathy of farmers' organizations. (38.)

IX. VARIOUS AGRICULTURAL INDUSTRIES.

A. Cereal growing.—1. Wheat.—Mr. NORRIS remarks an inclination in the West and Northwest to get land into producing wheat as fast as possible, because if a person wants to dispose of his land he must have it under cultivation. (328.)

Mr. Norris thinks the production of wheat is continually growing less in the East, so that some increase is necessary in the West to keep up the supply; but in some

years the production has developed more rapidly than the demand, resulting in lower prices. He says wheat can be grown in the Dakotas for 50 cents a bushel at more profit than in the East at 75 cents. (328, 329.)

Mr. BUDGE says the principal industry in North Dakota is grain growing. The Red River Valley is justly proud of being known as the bread basket of the world. The crops seldom fail. Even during occasional years of partial drought the moisture-storing capacity of the soil and the resisting qualities of the acclimated wheat plant are very remarkable. (845.)

Mr. BUDGE says plowing for wheat is done in the fall in North Dakota in order to get the crop in on time. Farmers do not wait for the frost to get out of the ground before seeding. The deeper the frost the better they like it; the moisture supports the crop. The land is ready for seeding without any further preparation. Wheat is cut with a binder, shocked, and thrashed out of the shock as a rule, though a good many farmers have stacks. A good thrashing machine will thrash 2,500 to 3,000 bushels a day. (851.)

Mr. JUMPER, of Aberdeen, S. Dak., knows of several farmers who have tried winter wheat in that section, but it does not come up in the spring. Unless there is a good deal of rain in the fall the ground will freeze out dry on top. (740.)

Mr. WEIDENBURN testifies that there is a good deal of wheat grown in the valley of Virginia and through the Piedmont section and some in southern Virginia. A little is grown in Loudoun and Fairfax counties. Corn is the principal Loudoun County product. Wheat does not pay in that section, though in that portion of Maryland adjacent to the District of Columbia very fine wheat crops are raised, the soil and climate being very much the same as in northern Virginia. In Fairfax County, Va., within a few miles of Georgetown, farmers have raised as much as 35 bushels of wheat to the acre. (625.)

The production of wheat in relation to the demand.—Mr. HANLEY testifies that the 70,000,000 people of the United States consume 400,000,000 bushels of wheat annually, or 5½ bushels per capita. (289.)

Referring to Mr. Atkinson's statement that the productive capacity of this country for wheat is sufficient to meet all demands of the world for the next 50 or 100 years, Mr. POWERS says the amount of wheat that would be produced in this country if the price were kept at a dollar a bushel in Liverpool could hardly be calculated. The amount we are capable of producing is immeasurable. (181.)

Dr. CROWELL says that when Europe has good harvests for a series of years the demand on the American surplus of wheat is very much less than usual, and over-production has made the low-price level more or less permanent. When the leading countries of Europe have a bad harvest there is a shortage and prices go up. America is in the position of a monopolist, because the Argentine and Australian harvests do not come at the same time as ours. (343.)

Mr. HIRCHCOCK testifies that India has not the importance it formerly had as a source of supply for wheat. The general tendency of wheat production in British India has been downward in recent years. (669.)

2. Corn.—Mr. PROM says corn is beginning to be raised in North Dakota; he is confident that before many years it will mature even in Cavalier County, which lies on a plateau, because the seasons are longer than formerly. The breaking up of the territory to the west gives the Red River Valley more heat, yet the hot, burning winds that strike South Dakota do not reach that section. (793.)

Mr. JUMPER says that corn matures nearly every year in South Dakota, but it is smaller than the Iowa corn. Farmers are increasing their acreage every year. (740.)

Mr. GAGE, of Memphis, says a good farmer is always supposed to make corn enough to supply his family and stock. All the little country towns have mills to grind corn. Corn is used a great deal for food. Where the farmers are able to, they buy flour to a great extent and sell their corn; one is about as cheap as the other. (492.)

Mr. HALE testifies that corn can be produced in Georgia at from 20 to 25 cents a bushel. His superintendent produced it one year at 17 cents and a fraction. (397.)

Mr. WILSON estimates the cost of raising corn and putting it in the crib in central and northern Illinois at from \$10 to \$11 an acre, including the interest on the money, land being valued at \$80 or \$90 an acre. The yield per acre in that section is seldom under 40 bushels, and some get 75; the average for Illinois is 26. The cost per bushel is from 20 to 25 cents. The cost of marketing varies with the locality. (251.)

Mr. TURNBULL says that corn is raised in some portions of California, but not generally. (984.)

3. Barley.—Mr. NORRIS says that formerly the price of barley was 70 to 75 cents, and often a dollar or more, but the price was reduced to about 30 or 35 cents. It no longer paid to raise barley in the best barley section of New York, and the people practically stopped raising it. In the town of Sodus, where 25,000 to 40,000 bushels

used to be grown, probably not 1,000 bushels were grown in 1899. There were formerly several very large malt houses in the county, but the trust closed up nearly all of them and began to buy Western barley. Mr. Norris thinks the adulteration of malt by the use of substitutes for barley has been the chief factor in destroying the barley-growing business, however. The importation of barley from Canada has had no perceptible effect upon prices, because of the duty, though the malsters claimed for several years that Canadian barley made a little lighter malt or a little more of it than the American (having a finer shell), in order that they might buy the best American barley at less than the Canadian price. (325.)

Mr. BUDGE says the yield of barley in the river counties of North Dakota ranges from 50 to 70 bushels to the acre. The price runs from 18 to 27 cents, depending on the quality, but averages about 20 to 25 cents for good barley; sometimes it goes to 34 cents. The farmers do not take care of their barley, but let it get bleached, and that reduces the price 2 or 3 cents. With care it would be a profitable crop. (852, 853.)

4. Cereals in California.—Mr. NAFTZGER testifies that the California wheat crop of 1900 was a little over 973,000 tons. The exports of barley from California were 212,000 tons. The production of other cereals is comparatively small. Very little corn is raised. The summer is too dry for corn, though there are limited areas of moist land near enough to the water level to produce it. Oregon and Washington, having a longer rainy season, produce more corn. (950.)

Mr. Naftzger says there is a wet and a dry season in California. The rains usually begin in November, sometimes earlier; but in central and northern California the rain puts the ground in condition for seeding by November, and the sowing of the cereals continues until midwinter. The rains continue at intervals until April, after which very little is expected. The wheat is ready for harvest by the 1st of June. It cures on the stalk, and is harvested from June until September. A good deal of barley is grown, the food for work animals being largely barley and hay. (966.)

5. Yield of cereals per acre.—*In the Northwest.*—Mr. MORAN submits a tabular statement showing the average yield of wheat per acre in Big Stone County, Minn., from 1890 to 1900, inclusive. The average number of bushels to the acre ranged from 24 in 1895 to 6 in 1893 and 1900. The average yield was 10 bushels. Mr. Moran thinks these figures would apply to the adjoining counties also. (707, 708.)

Mr. Moran testifies that the usual yield of from 8 to 12 bushels of wheat in Big Stone County, Minn., is obtained by continual cropping of the same land, without the use of artificial fertilizers or composts. The soil is dark loam, and is considered fertile enough without fertilizing. There is very little difference between the yield per acre during the past decade and the one preceding. On the breaking of the virgin soil in that district the crops are small the first year as compared with the second, and the second year as compared with the third, but beginning with the third crop they are fair. (708.)

Mr. JUMPER states the average yield of wheat per acre in South Dakota during recent years as follows: 1893, 8.5 bushels; 1894, 6.6 bushels; 1895, 12 bushels; 1896, 11.2 bushels; 1897, 8 bushels; 1898, 12.4 bushels; 1899, 10.7 bushels; 1900, 6.9 bushels; average, 9.5 bushels. (732.)

Mr. Jumper says the average yield per acre is reduced by shiftless farmers, who drag or scratch the seed in on the old stubble without plowing it once in 5 or 6 years. The field grows up partly to weeds, and perhaps half of it, and perhaps none, will be harvested. Ten years ago 20 or 30 per cent of the farming in the Dakotas was carried on in this manner, but these farmers have gone, or are farming better year by year. On the other hand, there are a great many farmers in South Dakota that produce 20 bushels an acre almost every year, and some get as much as 25 or 35 bushels. (733.)

Mr. PROM, of North Dakota, says that in 1895 there was a big crop of wheat, but in 1900 a small crop. The intervening years were average years, and the average yield has been 14½ to 15 bushels. (793.)

Mr. BUDGE testifies that the yield of oats per acre in the river counties of North Dakota is about 50 to 90 bushels. Oats are not as hard on the land as wheat. (853.)

In the South.—Mr. POWERS says that in the production of cereals in the South, generally speaking, much smaller crops are raised than in the Northwest. (171.)

Mr. WHITNEY testifies that the normal yield of grain is about one-third as great in the South as in the North, apparently because in the Northern States frosty nights occur at about the time the plant has attained its full growth, favoring the production of grain, as in all plants, when there is danger of destruction, the plant tends to reproduce itself by the formation of seed. In the South, on the other hand, with a higher temperature and greater humidity, there is a persistence of vegetable growth and less chance for the production of grain. (873.)

Mr. Whitney adds, however, that the largest yield of corn on record is from South Carolina, where the vegetative growth was checked by certain methods of cultivation, and the resulting yield was phenomenal. (873.)

Mr. NUNNALLY says about 10 bushels of wheat and 15 bushels of shelled corn are raised to the acre in Georgia. (457.)

6. *Cost of wheat production.*—*Minnesota.*—Mr. MORAN submits the following estimate of the average cost for 11 years of raising an acre of wheat in Bigstone County, Minn.: Plowing stubbles, \$1; dragging, 15 cents; seed, 75 cents; drilling or seeding, 30 cents; cutting or binding, including twine, 75 cents; shocking, 15 cents; stacking, \$1; thrashing, 60 cents; hauling to market, from 3 to 7 miles, 3 cents a bushel; interest on land worth \$20 at 7 per cent, \$1.40; tax, including road tax, 30 cents; total, \$6.40, or including the cost of hauling to market, \$6.70. The average yield per acre for 11 years was 10 bushels, and the average price for No. 1 Northern was 60¢ cents. The usual difference of 2 cents a bushel between No. 1 and No. 2 and between No. 2 and No. 3 makes the average 58½ cents a bushel. (707.)

South Dakota.—Mr. JUMPER submits statistics of the cost per acre of raising and marketing wheat in South Dakota. He explains that the figures given are less than those given by Mr. Moran, because they are based on wheat headed and put in the stack, while Mr. Moran's were based on wheat cut by the binder, then shocked, and stacked and thrashed from the stack, which is possibly \$1.25 an acre more expensive. Moreover, Mr. Jumper does not include interest on the value of property, but commences with the preparation of the ground and ends with the wheat at the elevator, allowing average wages and including 16 cents for taxes, but nothing for wear and tear of machinery. The average cost of production of wheat is stated as follows: 1893, \$3.45 an acre; 1894, \$3.25; 1895, \$3.80; 1896, \$3.90; 1897, \$3.95; 1898, \$4.25; 1899, \$3.90; 1900, \$3.70; average, \$3.77. (732.)

North Dakota.—Mr. BUDGE, of Grand Forks, N. Dak., estimates the cost of raising wheat and putting it on the cars at about \$5 an acre. (849.)

Mr. PROM testifies that it costs about \$5.72 an acre to raise wheat in North Dakota, not including interest on the land. There is a margin of profit. (793.)

7. *Does it pay to raise wheat?*—The question as to whether wheat farming is profitable in western Minnesota at 10 bushels an acre at the average price of the past decade is answered by Mr. MORAN in the negative; "the more wheat we grow, the poorer we get." The settling of the country increases the value of the land, however. (708.)

Mr. Moran testifies that his estimates of cost of production (see IX, A 6 above) represent the lowest price at which the work could be done, and that in comparison with the price of grain they show that grain is raised at a loss, allowing a reasonable remuneration for the farmer's time. With land at \$20 an acre, which is about the average price in his vicinity, and allowing interest at 7 per cent, the witness fails to see how a young man can get a foothold raising wheat. (710.)

Mr. GREELEY, of South Dakota, says the farmers of that section can not make it pay to raise wheat year after year; they lose crops by hail and drought, and if they have no stock, the year's income is gone. Wheat exhausts the soil, and does not pay unless it is brought in incidentally in rotation with stock farming. The attention of the whole Northwest is turning more to stock. This will decrease the wheat production for a time, but Mr. Greeley knows of farmers who are raising more grain than before they put the stock on the farm, because their farms are cleaner and richer. With good stock farms the Northwest will continue to be the "granary of the world." (938.)

Mr. BUDGE, of Grand Forks, N. Dak., says that when a man cultivates his farm rightly it is profitable to raise wheat. The price averages about 60 cents. (849.)

Mr. JUMPER finds the profit per acre from wheat raising in South Dakota, or the difference between the cost of production and the average price of each crop, to have been as follows: 1893, 21 cents; 1894, 49 cents loss; 1895, profit of \$1; 1896, \$2.03; 1897, \$1.97; 1898, \$1.95; 1899, \$1.45; 1900, 30 cents; average, \$1.05.

Mr. Jumper estimates that the average amount of wheat raised in his section on 160 acres would be 1,200 or 1,250 bushels, giving a clear profit of about \$275, after allowing good wages. Mr. Jumper denies that the more wheat a man grows the poorer he gets. He says he can cite many thrifty farmers in Brown County who have added more land to their farms by raising wheat, but they have grown much more wheat than the average. (732, 733.)

Mr. TURNBULL states that it is thought by experts in the business that wheat can not be raised at a profit in California. Many of those that have been largely in the business are quitting it and cutting up their farms for fruit. The largest yields would be about 30 cents or 50 bushels an acre on the Sacramento bottoms. That is an unusual crop. A good average crop for a fair year would be 15 or 16 cents, or 25

to 27 bushels. The trouble is that such a crop can be obtained only about twice in 5 years. The other 3 crops would probably not be one-fourth as great; so the farm would run 3 years at a loss and 2 at a profit. This is because of lack of water. (970, 983-985.)

8. Grain markets.—Mr. WILSON, of Magnolia, Ill., says the grain from that section goes to Chicago for the most part, though grain is shipped to the Gulf to a considerable extent. (252.)

Mr. PRATT, of Aberdeen, S. Dak., says that when he was first in the wheat business the wheat was shipped to commission houses in Milwaukee. Afterwards Chicago was the market for wheat from the South and Southwest, and Minneapolis the market for Dakota. Twenty or 25 years ago a great many country buyers bought up grain and shipped it on their own responsibility to elevator companies, putting up cheap houses along the track. The grain was handled by sample. (726.)

Mr. MORAN, of Graceville, Minn., says he generally sells his grain under the quotations of the Minneapolis market, which are sometimes lower and sometimes a little higher than the Chicago quotations. (713.)

Mr. PRATT, of Aberdeen, S. Dak., says the buyers of wheat in that section ship to Minneapolis principally, and the price is set mainly by Minneapolis people. Even if the Duluth market is better than the Minneapolis market the wheat goes to Minneapolis, but some cars go right on to Duluth. The heads of the Minneapolis firms will order it to Duluth; they can make a deal with the Duluth people at any time. The local buyers on the Great Northern road, however, very seldom ship wheat to Minneapolis, but ship to Duluth. There are no Milwaukee or Chicago buyers in that section. (727, 728.)

Mr. JUMPER, also of Aberdeen, S. Dak., says the wheat from that section is nearly all unloaded and sold at Minneapolis, because the price there is about equal to Chicago prices; a farmer would lose 2 or 3 cents a bushel by shipping to Chicago. Some of the wheat goes direct to Duluth for transshipment by the lakes and export. Mr. Jumper knows of no instances of shipments to New York, because the difference in price between Minneapolis and New York is very much less than the freight. The farmers never ship wheat to Chicago or Milwaukee, because Minneapolis and Duluth are much better markets. The price in Minneapolis is more than the price in Chicago, taking the freight into consideration, because of the local consumption by the mills in Minneapolis. (739, 740.)

Mr. PROM says the shipments of grain from Cavalier County, N. Dak., are very often divided between Minneapolis and Duluth, the freight rate being the same to both points—15½ cents per 100 pounds. At times there is a difference of 2 cents in favor of Duluth, and at other times of the year Minneapolis is higher. The best grades of wheat go to Duluth; the poorer grades generally go to Minneapolis, and are mixed with better grades. (795, 796.)

Mr. PRATT says that it is impossible to ship wheat to Liverpool so as to keep each grade separate, as some schemers have proposed. It is mixed before it starts across the ocean, and the whole cargo shipped in bulk. (727.)

9. The manufacture of flour.—Mr. REDDING testifies that there are some roller mills in northwestern Georgia, the wheat-growing section of the State. They are being established even in middle Georgia. Quite an interest in wheat has been created within a few years, centering largely about Macon. (447.)

Mr. Redding thinks the establishment of local flour mills would doubtless tend to increase the demand for the Georgia wheat crop. There are a great many old-fashioned merchant mills now idle or only grinding corn which could be equipped for grinding wheat. (448.)

Mr. TURNBULL states that all the flour used in California is manufactured there from California wheat, and a large amount is also manufactured for shipment to Asia. This trade is rapidly growing. (983, 985.)

10. Prices of wheat.—*Reasons for low prices.*—Dr. CROWELL attributes the decline in the price of wheat to (1) transportation facilities, and (2) the great increase in production due to the application of agricultural machinery to cheap, rich land. A great decline has occurred since the development of the wheat-growing section of America. Dr. Crowell submits a diagram from the final report of the Royal Commission on Agriculture, showing that from 1849 to 1872 the production of wheat increased 70 per cent and the price increased 30 per cent, while from 1872 to 1894 the production increased 40 per cent and the price decreased 60 per cent. (341, 342.)

Recent price movements.—Mr. COLES, of New Jersey, testifying in June, 1899, stated the price of wheat in New Jersey was about 85 cents. The previous summer it was about 75 cents; the year before that, somewhat higher, and the year before that about 65 or 60 cents. The average price for the years of 1897 to 1899 was higher than for some years previous. He thinks the average wheat crop in his section in

1898 was 18 bushels and in 1897 22 bushels. He does not regard wheat as a paying crop in that section, though it is sometimes necessary to grow it on account of the straw. (127.)

Mr. POWERS says that in Minnesota, the center of the wheat area, the gold value of wheat on the farm, as given by the Agricultural Department for 5 years about the close of the war, averaged about the same as in recent years, or a little less. Wheat at the center of production has remained substantially unchanged in price. (188.)

Mr. HANLEY says that the average price the farmer gets for wheat in the wheat belt is in the neighborhood of 50 cents, although the price quoted is generally about 70 cents. The price of wheat July 1, 1899, was 52 cents at Viborg, S. Dak., about 275 miles from Minneapolis; about 45 cents at a distance of 400 miles, and 60 cents at a distance of 150 miles from Minneapolis, or, on an average, about 55 cents in the wheat belt of the Northwest; while in Minneapolis the price was 69½ cents, in Duluth 72½, in Chicago 73, and in New York 78½. The cost of producing a bushel of wheat being 50 cents, it costs about one-half that cost to carry it to the Atlantic seaboard, including freight charges, storage, insurance, loading and unloading, etc. (280, 287.)

Mr. MORAN testifies that there is usually a difference of 10 cents a bushel between the price of wheat in Graceville, Minn., and the price paid in Minneapolis, and he attributes the difference to freight rates, elevator charges, commissions, etc. (708.)

Mr. Moran submits a statement of the average price of No. 1 Northern wheat at Graceville, Minn., from 1890 to 1900, inclusive, showing a maximum of 84 cents in 1891 and a minimum of 44 cents in 1895, increasing to 72 cents in 1897 and 65 cents in 1900, with a reaction in 1898 and 1899. Mr. Moran says the climate had a good deal to do with the low prices of wheat from 1892 to 1896. The largest crop ever produced in Big Stone County, Minn., was in 1895, the season being very favorable. The year 1900 was extraordinarily dry, and the crop was small in consequence. (707.)

Mr. Moran testifies that he has sold wheat in his young days as high as \$1.37, and might have sold it as high as \$1.50 if he had sold at the right time. The contrast of these figures with 50 and 55 cents shows a vast difference in the opportunity presented to a young man. (710.)

Mr. JUMPER, postmaster at Aberdeen, S. Dak., submits statistics of the average monthly price of wheat at that point from August, 1893, to December, 1900, and the following averages for the crop years and for the first 6 months, August 1 to February 1, when nearly all the crop is sold:

	1893-94.	1894-95.	1895-96.	1896-97.	1897-98.	1898-99.	1899-1900.	1900 (5 months).
	Cents.	Cents.	Cents.	Cents.	Cents.	Cents.	Cents.	Cents.
Crop year	43½	46	42½	55	80½	53	52½	58
First 6 months	43	42	40	53	74	60	51	

Mr. Jumper explains that the price of wheat was about 2 cents higher in North Dakota and about 5 cents higher in Minnesota than the figures he gives for Aberdeen, on account of nearness to Minneapolis and to the Duluth market, which is usually 1 or 2 cents higher than the Minneapolis market. The prices at the different stations are adjusted according to the difference in freight, being lower or higher according as freight is higher or lower. (729-731.)

Mr. PROM says that during the last 6 years the average grade of North Dakota wheat has been No. 2, and the average price for that grade 55 cents. (793.)

11. *Rice.*—*South Carolina and Louisiana.*—Mr. WHITNEY says the rice lands of South Carolina were protected before the war by substantial levees, built through cooperation between individuals and the State. During the war these levees were destroyed, and since then it has been impossible to get labor to work in the canals on account of the unhealthfulness and other conditions, and large areas of this once extremely productive land have been abandoned. The rice lands of southwestern Louisiana, which were semiswamps, have been drained where necessary, and are not subject to overflow as the rice lands of South Carolina are. The Louisiana lands are higher and more healthful than those of South Carolina and are irrigated by pumping or by artesian flow, while the rice lands of South Carolina are flooded by the rivers, without artificial means. (864, 865.)

Dr. STUBBS says the production of rice in Louisiana has increased enormously in recent years, and more rice is now produced in that State than in all the others together. Until 15 years ago the rice fields of Louisiana were practically worthless and were used for cattle and ponies, but they were discovered to be valuable for

CCXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

rice and have been redeemed. A good deal of the land belonged to the United States and a great deal to the State, being swamp land. The lands have all been bought, and are now being exchanged at \$30 and \$50 an acre. Rice cultivation in Louisiana is now extremely profitable, particularly in the southwestern part, where improved implements can be used. (773.)

Rice irrigation in Louisiana.—Dr. STUBBS says it has been found necessary for profitable rice culture that the fields should be covered by water. Five or 10 years ago probably one-third of the rice grown in southwestern Louisiana was Providence rice. All the water falling is retained by a substratum of clay and by an embankment around the field. This made possible the production of considerable quantities of Providence rice for 1 or 2 years, but in dry seasons nothing was made, and the Providence rice has been abandoned entirely. Rice is now grown exclusively by flooding, and the immense amount of money spent in constructing canals for flooding the rice fields from the nearest streams has contributed to the abandonment of the Providence process. Dr. Stubbs estimates that at least \$5,000,000 have been spent in that way. There are 300 miles of these large rice canals, some of them 30 miles long, and every tributary farmer draws water. The fields are usually overflowed when the rice is about 6 inches high, unless conditions require flooding to get the seed up. The water is kept on the land until harvest time, when it must be allowed to dry sufficiently to permit the use of binders. The country being very level an 80 or 100 acre field can be inclosed within a levee and improved implements can be used to great advantage, though along the river the binder can not be used to advantage, because levees are required at frequent intervals and the sickle is used there for harvest. The levees are arranged in either case so as to get the water from 4 to 6 inches deep over the rice field.

Dr. Stubbs has heard no complaint of the climate of Louisiana on account of the flooding of the rice fields. The climate is regarded as extremely healthful. At a recent election there were 7,000 voting Northern men there who seemed to be healthy after from 1 to 15 years' residence. The summer is very cool and pleasant, though the land is not more than 10 to 50 feet above the Gulf level. There is rarely a frost, and the climate is delightful. Among the creoles there are as many octogenarians as anywhere else in the world. An abundance of the purest drinking water is obtained from artesian wells. (772, 773.)

Seedtime and harvest.—Dr. STUBBS says rice is planted in Louisiana through April and May, and harvested from the last of July up to about the middle of September. The rice planters have far more leisure than the cane planters. The rice is thrashed whenever one of the traveling thrashers can be obtained. Large rice owners have their own thrashers, and commence thrashing as soon as the rice is cut. (775.)

High-grade rice most profitable.—Dr. STUBBS testifies that, good head rice being worth much more than the lower grades, the rice which gives the largest amount of head rice gives the greatest profit to the farmer. (772.)

Rice mills.—Dr. STUBBS declares there is hardly a village of 500 inhabitants in the rice district without a first-class rice mill. The farmer either sends the rough rice to be milled at his own expense or for toll, or sells it in the rough. The mills are ready either to buy it or to work it up on toll. They convert the rough rice into the various grades, from head rice to broken fragments. (772.)

Revival of the rice industry in the Carolinas.—Mr. MEAD testifies that the success of rice irrigation in Louisiana, after a long period of continual shrinkage in production, has led to an increased interest in rice growing on the Atlantic seaboard, where old canals were going out of operation. The question now is whether the Louisiana method can be adopted there.

Rice cultivation in the Carolinas is largely after the methods prevailing before the war, the crop being cut with a sickle and bound by hand. He says the reason it is so much more successful in Louisiana is because of the application of modern machinery. (See also *Agricultural implements in the South*, I F 3, Stubbs, p. xciv.) The crops there are cut with a self-binder, economies have been in the field of labor, and the methods of applying and distributing the water are patterned after those of the West rather than those of the Carolinas. There is an economy in the distribution of the water, as well as in the harvesting of the crop; thus the industry has been made exceedingly profitable. (1069, 1070.)

B. Cotton.—1. *Production at home and abroad.*—Mr. WEDDERBURN says the United States has practically no competitor in cotton at the present time, but the industry is developing in the Russian steppes, where he fears we shall in time have a great competitor. (632.)

Mr. BARRETT says the amount of cotton produced in the United States in 1898 was 11,200,000 bales. The estimates of the Chinese crop are uncertain. American cot-

ton is gradually driving Chinese out of European markets, and to some extent even out of its domestic market. The fiber of the Chinese cotton is not strong enough to stand spinning machinery. (57, 58.)

2. Methods of cultivation.—Mr. Radding testifies that cotton is hoed in Georgia just as formerly, and costs about as much to produce as it did 40 years ago. The improvements are usually in the selection of seeds and fertilizers and the preparation of the land. The principal item of expense is gathering the crop. (453.)

3. Varieties of cotton.—Dr. Stubbs says the production of sea-island cotton per acre is less than of upland, and there is an increased cost. It is nothing unusual to make a 500-pound bale of upland cotton to the acre; it is something extraordinary if that amount of sea-island cotton is obtained. It is also extremely difficult to maintain the long staple. The planters who get 50 cents a pound for their cotton select their seed with the greatest care, and maintain the selection every year; but where it is grown carelessly, as in southern Georgia, the price is rarely more than 15 to 18 cents a pound; the length deteriorates very rapidly under careless cultivation.

Charleston and Savannah are the markets for sea-island cotton; there is no sale for it in the other Southern cities. In 1899 and 1900 sea-island cotton was shipped from one of the Louisiana experiment stations and the prices obtained were from 17 to 30 cents, while the prices were about 14 to 50 cents for ginned cotton.

Dr. Stubbs adds that the upland cotton is baled in the press at the ginhouse. The sea-island cotton is put in long bags and packed down by tramping until a bag weighs from 300 to 400 pounds.

Dr. Stubbs thinks there is abundant room for spreading the cultivation of sea-island cotton; but sea-island cotton is very objectionable to an upland cotton man, because it is extremely difficult to pick. It grows very tall, and the yield of lint is very rarely more than 20 to 24 per cent. It is difficult to grow it unless the hands are accustomed to it. The long-lint cotton has only 3 lobes, with projecting horns which the picker gets in his hands, and a good picker of upland cotton will be a very slow picker of sea-island cotton. It is also necessary to have a roller gin for long-staple cotton, whereas all short-staple cotton is ginned with the saw gins, which are extremely rapid, while the roller gin is very slow. The saw gin tears the seed off, while the roller gin or knife gin cuts the fiber away from the seed without destroying the fiber at all. To pass from upland cotton to sea-island cotton is almost as great a transformation as going from cotton to cane. The Egyptian cotton is woolly, coarse, rather long staple, and has a creamy tint and a peculiar finish. It is used largely for making ballbrigan underwear, hence the introduction of Egyptian cotton can not be suppressed. The merchants demand it. Six or seven million dollars' worth of the cotton is introduced every year. The manufacturers have tried hard to find a Southern cotton that would take the place of it, but have not succeeded.

The growing of Egyptian cotton, according to Dr. Stubbs, is a question of irrigation. It is grown in a very dry climate and irrigated periodically, and it is impossible to acclimate it in the damp climate of Louisiana and get the same result. The Egyptian cotton was originally the sea-island cotton of our coast, but it has been differentiated by climate until it comes back an entirely different cotton. Any attempt to acclimate it will result in its going back to long-staple cotton. The only part of the United States favorable for the production of Egyptian cotton is the arid section of Texas, and it must be periodically irrigated.

The long-staple cotton is confined exclusively to southern Georgia, including the islands on its coast, South Carolina, and certain parts of Florida. Dr. Stubbs has tried for 8 or 10 years to grow a long-staple cotton somewhat resembling Egyptian cotton at the Louisiana experiment station, and by distributing seed to planters, but it has been a failure. He got 8 or 10 kinds of Egyptian seed, including some of the purest, and an English roller gin like the one used by the experiment station in Egypt. He saw that the cotton was cultivated exactly as it is in Egypt. As a result he has 2 bales of home-grown Egyptian cotton, which have been sent to Boston to see what can be done with it. It ought to compare with the imported Egyptian cotton, but the yield is too small for profit.

Peruvian cotton is a perennial or tree cotton, and does not bloom until the second or third year; it would not survive our winters, and can not be introduced in the South successfully because it will never bear seed. Dr. Stubbs has 2 or 3 stalks of it under glass. (785-787.)

4. Yield per acre.—Mr. NUNNALLY, a cotton planter of Nunnally, Ga., cultivates between 300 and 400 acres and runs 9 plows. In 1899 he made 65 bales, or 1 bale to about 2½ acres; the year before he made a bale to every 2 acres, which is generally his estimate of the crop. If he can get 2 acres to make a bale he considers it very good farming. (453, 454.)

Mr. MANSON, of Saulsbury, Tenn., estimates that the average yield of cotton in his

county is about 1 bale to 4 acres. No fertilizers had been used until 1900, when Mr. Manson expressed the intention of trying the experiment. (506.)

Mr. KYLE, of Mississippi, testifies that in the vicinity of Friar Point, in the Delta, the yield of cotton is rarely less than 1 bale or 500 pounds of lint cotton to the acre. In the hills the yield is less. (464.)

5. *Cost of production.*—Mr. HAMMOND, a cotton planter of South Carolina, states that a careful estimate of the cost of raising cotton in the Pedee region of South Carolina, made in 1848, showed the cost to be 4.7 cents a pound, including interest at 7 per cent on the full value of the capital employed. In 1886 Mr. Hammond collected itemized statements of the cost of cotton production from 12 of the best cotton growers of this region. They range from 6.1 to 15.22 cents, the average being 8.28 cents. The lowest possible cost that Mr. Hammond has been able to figure without any profit whatever, is \$5.88 per hundred. Down to 1895 the East Indian crop declined after the price reached 11½ cents, and the Brazilian and West Indian after the price fell to 14 cents. Only in Russia, on account of the unusual development of agriculture, and in Egypt, because of the peculiar character of the staple, has the production increased since cotton fell below 11 cents. The margin of safe cost in cotton growing is about 9 to 11 cents a pound. The large crops that have been grown at much lower prices have been grown under the artificial stimulation of a ruinous credit system. Other property has been swallowed up to maintain the growing of cotton. The orchards, the gardens, the sheep, the cattle, the horses have been swept away, and Mr. Hammond can count, within a radius of from 3 to 4 miles from his door, 11 houses once inhabited by substantial and prosperous families, which are now empty or occupied by negro tenants, with the land divided into small cotton patches cultivated by negroes on the edge of want. (827, 832, 838.)

Mr. NORFLEET, of Memphis, testifies that the cost of producing cotton has been reduced very materially of late years; the methods of cultivation are better, and the price of labor has fallen very materially since the war. During the high-priced days planters paid from \$1 to \$1.50 a day for labor, and from \$200 to \$250 for mules, and lands were worth \$15 to \$25 an acre, so they made no more money than they do now. (485.)

Mr. Norfleet estimates the cost of raising cotton as follows: Cultivation, \$5 an acre; use of mule, \$25, or \$1.25 an acre; use of gear and plows, 50 cents an acre; corn for mule, \$30 a year, or \$1.50 an acre; fodder or hay, \$1.60; rent of land, \$5 an acre as an average; picking, \$8 a bale, or two-thirds of that amount to the acre; hauling to the gin and handling, 60¢ cents an acre; ginning and tying, about \$2.50 a bale, or two-thirds of that amount to the acre; total, \$22 an acre, for two-thirds of a bale. (489, 490.)

Mr. Norfleet says planters can not raise cotton for 5 cents and prosper. When they have to take low prices for cotton they fail to make any further improvements on their places, and their houses, fences, utensils, etc., run down. (490.)

Mr. MANSON, of Saulsbury, Tenn., testifies that if a man pays \$8 a month for hired help he can not raise cotton for less than 7 cents on land producing about one-third of a bale to the acre. He doubts whether even in the Mississippi bottom cotton can be raised at 5 cents a pound. (507.)

Mr. HILL, a cotton dealer of Memphis, thinks the actual cost of raising cotton near Memphis is about 5 cents, and in the hill country about 6 cents, exclusive of the wear and tear on the farming implements and interest. He says the cost of raising cotton has increased with the increased prices between 1898 and 1900. (503.)

Mr. GODWIN, of Tennessee, estimates that it costs \$5 an acre to cultivate cotton up to the time of picking. The average price of picking in his neighborhood is 50 cents a hundred pounds, or \$8 for 1,600 pounds of seed cotton, which makes a bale of lint cotton and 1,100 pounds of seed. The customary price for ginning, if the planter does not furnish the bagging and ties, is \$2.50 a bale. On the basis of one-third of a bale to the acre this would make the cost of production \$8.50 an acre, or, including the hauling of the cotton, say \$9.50 an acre. Deducting \$2.40 an acre for seed sold would leave \$7.10, or about 4 cents a pound, as the net cost of producing lint cotton. It costs less in the Delta than in the hill country, but it seems to cost more to live and run a plantation there. (477, 478.)

Mr. KYLE, of Mississippi, estimates that the average cost of growing cotton when corn, mules, and farming implements were cheap was \$20 to \$25 a bale, or 4 or 5 cents a pound. He does not believe cotton can now be grown for that price (March, 1900) because mules, horses, plows, and all kinds of hardware are worth more. (466, 467.)

Mr. BALCH confirms Mr. Kyle's testimony to the effect that at 5 cents cotton can not be raised with wage labor. At the price prevailing in March, 1900, it could be, though farm labor had also advanced a little. (496.)

Mr. REDDING, director of the Georgia Agricultural Experiment Station, says it

costs all the way from $3\frac{1}{2}$ to 20 cents to raise cotton; the average cost for the past decade or two has been about the market price. A great many farmers do not make any money at all. (445.)

Mr. PEEK, of Georgia, testifies that when 1 bale of cotton is made to 3 acres it costs about $8\frac{1}{2}$ cents, including the expense of delivering at the station and interest and taxes, but not counting the labor of the farmer's wife and children. When 1 bale is raised to 2 acres the cost is about $7\frac{1}{2}$ cents, and when a bale is raised to the acre it can be made for about $6\frac{1}{2}$ cents. (457, 458.)

Mr. HOLMES testifies that the cost of raising cotton has been determined by the Department of Agriculture to be 5.27 cents a pound, but the price of cotton at the plantation has of late gone below this figure. (160.)

Mr. HANLEY says the average price of cotton in 1898 was 6.22 cents a pound. The Agricultural Department gives the cost of producing a pound of cotton as 6.4 cents. The cost of marketing the crop amounts to about 2 cents a pound. This means a net loss to the Southern planter of more than \$100,000,000 on the crop of 1898. (289.)

Where \$6 a month is paid for labor, Mr. BARRETT says, it costs over 6 cents a pound to raise cotton. There are various other items which the cotton raiser is forced to pay which depress his profits. Thus the cost of bagging and ties, which averages about 85 cents a bale, is an absolute loss. The amount deducted for tare in Liverpool is 30 pounds a bale, although the actual tare is little over 24 pounds a bale. The so-called "country damage" is also deducted in Liverpool, amounting to about \$500,000 for the entire crop. (50.)

Mr. LOVEJOY says that there was profit enough to the farmer when cotton was sold at 8 to 10 cents per pound, but there is little profit when it falls below 7 cents. It can not pay expenses when the price is less than $5\frac{1}{2}$ cents. (75.)

Georgia and Texas.—Mr. BARRETT says that although the soil of Texas is more fertile than that of Georgia, requiring no fertilizer, the cost of labor is fully twice as great in Texas, and the success of the cotton crop is much less certain. Mr. Barrett believes that so far as labor is hired in each State Georgia can raise cotton as cheaply as Texas, but she can not compete with the labor of white owners of land. (57.)

6. Marketing of cotton.—Mr. GRAHAM, of North Carolina, says cotton is nearly always sold to the manufacturer. Mr. Graham's custom is to telephone to the mills for the price. He has made half a cent a pound by the use of the telephone. When cotton is low the price is nearly always higher in North Carolina than in New York. There is frequently a difference of a cent between the Charlotte and the New York prices. The farmer benefits by the presence of local mills. (436.)

Mr. REDDING thinks most of the cotton of Georgia still goes to New York. That which is sold in the local market does not have to be hauled very far; perhaps 5 miles would be the average. (453.)

Mr. KYLE, of Sardis, Miss., says the cotton from that section is now generally sold to exporters, and goes to New Orleans. The planters sell at home to anyone who will buy, and sometimes the mills send a man to the interior towns to buy cotton. Sometimes it is shipped to the cotton factors at Memphis. (473.)

Mr. GODWIN, of Tennessee, testifies that he sends his cotton to cotton factors—that is, commission merchants—in Memphis, who sell it to Eastern spinners and to exporters, charging about $2\frac{1}{2}$ per cent commission. Cotton can be sold by the farmer on the street, but the cotton bought on the street in Memphis is as a rule bought by people who do nothing else; they put the cotton in the warehouse, sample it, and put the samples on some factor's table to sell. If a man sells from the wagon he expects to sell at $\frac{1}{8}$ to $\frac{1}{4}$ less than if he turned it over to the factor and let the factor have time to sell on the market. The factor sells to people who can pay full price. (480.)

Mr. PORTER, a cotton broker, testifies that Memphis is the largest inland cotton market in the world. Cotton is shipped from there by way of New Orleans, Pensacola, Brunswick, Norfolk, Boston, New York, and other ports. (483.)

Compressed and uncompressed cotton.—Mr. Porter says the cotton shipped from Memphis to the East and for export is compressed, but cotton is frequently shipped to South Carolina uncompressed. There are about 25 bales of uncompressed cotton to the car. Compressed cotton will run from 55 to 60 bales to the car. The railroad rate to Lowell is 10 cents a hundred lower on compressed cotton than on uncompressed. It makes no difference in the value of the cotton to the mill whether it is compressed or not, but the South Carolina mills prefer it uncompressed. (482.)

7. The decline in price.—Mr. PEEK, of Georgia, testifies that immediately after the war the price of cotton was high, but that since 1872 it has been falling gradually. After the election of 1892 it jumped to 10 cents; the crop of 1898 sold principally at about 4 cents; Mr. Peek began selling the crop of 1899 at 5 cents, and sold some as high as $6\frac{1}{2}$ and 8 cents. (458.)

CCXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. NORFLEET, a cotton factor and farmer of Memphis, Tenn., testifies that since 1870 cotton has gone from between 16 and 20 cents down to 4 cents. (485.)

• Mr. YOUNG, of South Carolina, says that all his debts were contracted on a basis of cotton at 7 cents a pound, but when he sold his crop the price did not average more than 4½ cents a pound. Consequently he met with a loss, and so did every man who advanced on the cotton crop. With some reactions, cotton has been declining since 1873. It sold in 1871 at 20 cents a pound, and has declined 75 per cent. Mr. Young thinks the average decline in prices has been about 50 per cent. (118.)

Mr. GODWIN, of Tennessee, testifies that his cotton crops of 1897 and 1898 brought about 5½ cents, on an average. The price was higher in 1896, and still higher in 1895, because the crop was smaller. The price of the crop of 1899 opened in the fall at about 6 cents, and gradually increased until on March 22, 1900, it was 9⅞ for middling cotton, or 9¼ or 9½ for good middling. The Delta cotton, having a longer staple and being better for export than the hill cotton, sells for ½ to ¾ of a cent more. (478-480.)

Mr. NORFLEET says that when cotton was sold at 5 and 6 cents a pound, cotton factors carried over unpaid accounts in many instances, though some planters were able to pay. The success of a plantation depends upon the supply of labor and the management. (491.)

8. *Efforts of planters to control prices.*—Mr. HOLMES says that for many years cotton planters have held conventions at irregular times with the express object of limiting the production of cotton and raising its price, but these conventions have never accomplished anything. (159.)

Mr. STEVENS says there has been a very successful effort made in Georgia, in connection with other Southern States, to control the price of cotton, and these efforts, together with the greater demand made by local mills, have given promise of very satisfactory prices. (916.)

9. *The recent advance in price* (see also *Recent Southern prosperity*, I B, p. LXXXIII).—Mr. REDDING says the prices of cotton in 1894 and 1895 were 4½ and 5 cents; in 1897 and 1898, about 5, 5½, or 6 cents. He estimates that the farmers realized on an average about 7 cents for the crop of 1899. Some sold before it got to that point, and some held on until it got to 8 cents. The advance was not of much benefit to the farmers, because they incurred obligations in the spring maturing in October or November. Probably not more than 15 or 20 per cent of them were able to hold the crop. (444.)

Mr. PORTER, a cotton broker of Memphis, testifies that the price of the cotton crop of 1899 started at about 6 cents and ran up to 12½ cents. He attributes the high price of cotton in the spring of 1900 to a short crop. (483, 484.)

Mr. KYLE says that while cotton was so cheap people found a great many new uses for it, as for mixing with silk and flax, and this, together with the shortage of the crop, increased the price. (466.)

Mr. Kyle thinks the cotton crop of 1899 was better in Mississippi than almost anywhere else. The crop was made with less money than before, with the idea that the price would be only 5 cents. All labor was furnished on that assumption, and food was cheap. The result was that when the crop paid from 6½ to 9 cents a pound there was a somewhat prosperous condition. (473.)

Mr. POOLE says that for the last few years the production of cotton has been very profitable, and Alabama farmers have been stimulated to cultivate an increased acreage. (925.)

Mr. GAGE, president of the Memphis Cotton Exchange, testifies that while the farmers in the vicinity of Memphis did not raise as much cotton in 1899 as for the two years previous, the advance in the price enabled them to realize more net income from the crop. There was more money in circulation; people were not asking for as large advances as in former years, and were not asking for advances so early in the season. (491.)

10. *Overproduction.*—Dr. STUBBS says cotton has been depressed for years, until 1899-1900, by overproduction or underconsumption. The enormous crops depreciated its value everywhere and reduced the price on the plantation to 4 cents, a price at which it is utterly impossible under the best system to produce it at a profit without starving the labor to death. Dr. Stubbs predicts that the present high price of cotton will induce overproduction again. (782.)

Mr. STEVENS says there was an overproduction of cotton in Georgia for a few years, about 1897 and 1898, but the increase of cotton mills in that State and in the South generally has made a repetition of that condition almost impossible. There has also been underproduction of grain and general farm supplies; but cereals are more largely planted than formerly, and the acreage under cultivation has increased because of

the diversification of crops. The effect of underproduction has been to increase prices, as farmers, because of the raising of supplies, have been able to control the sale of both their cereals and cotton. The prices of wheat and oats have advanced and the price of cotton has greatly increased. (915.)

Mr. KYLE, of Mississippi, attributes the decline in the price of cotton to two immense crops in successive years, an accumulation of manufactured goods, and the depressed condition of business.

Mr. BARRETT does not believe that overproduction is the cause of the low prices of cotton or of any other agricultural product. There would be a demand, if all people were employed, for an indefinite production. The largest cotton crop ever produced in this country brought the most money. (57, 58.)

Mr. PEEK, of Georgia, attributes the low price of cotton to the lack of money (banks paying no attention to the farmers) and to the cry of overproduction. The advance he attributes to the short crop and to the world's coming to the conclusion that there was no oversupply. (458.)

11. Cylindrical bales.—Mr. BARRETT believes the use of round bales to be more economical for the farmer in the South than the square or American bale. The best round bale is the Lowry, which is packed in the spiral manner. This form of baling saves 45 cents per 100 pounds, in the cheaper cost of the bale itself, and in the fact that no tare is deducted, tare on American bales amounting to from 24 to 30 pounds. The actual cost of packing a 500-pound bale on the Lowry system, including all items, is \$2.40. It is impossible to steal cotton from a Lowry bale or to mix in impurities and increase the weight fraudulently. The charge for the use of all forms of baling machinery, which are covered by patents, is excessive. (50, 51.)

Dr. STUBBS says everyone recognizes the merits of the round bale; it dispenses with a great amount of bagging and ties, it condenses and prevents the increased cost for the press at the shipping point, and has many other advantages. Thus far there has been a royalty of \$1 a bale for using the machine, besides other expenses; but Dr. Stubbs understands that the machines are to be for sale.

Thirty pounds are discounted in every bale of raw cotton, though we are not generally aware of it in this country. As soon as the cotton gets to England 6 per cent is thrown off as tare. The price is telegraphed back from Liverpool and the local merchants rearrange it so as to cover the whole bale. Planters can therefore afford to pay more for the round bales, where they lose only about 2 or 2½ pounds to the bale. There is also a saving in insurance and a saving in compressing. The big roller gin is easy to run and does not require a very large horsepower.

The big bales have to be compressed at 50 cents a bale. The condensed round bales are not inflammable; Dr. Stubbs has seen tests where they have been covered with kerosene oil and set on fire, but only charred. He is told that the fiber is not injured by the pressure. Mr. Atkinson writes him that by the recent introduction of a machine by which the cotton is unrolled from 5 or 6 bales at the same time and fed to the spindles or pickers the round bale has become popular. Before that there was difficulty in unrolling the bale. Formerly the old big bale was simply uncovered, drawn out, and picked, and thrown into the pickers.

There are now half a dozen or more different round bales. An antagonism has developed against them because of the large amount of money invested in public gins and compresses; at every crossroads in the hill country there is a large gin which will probably take the crop of 30 or 40 small farms. The only question at issue between the round bales has been which was the greatest monopoly and would squeeze the planters most.

Dr. Stubbs says the Lowry bale is a spiral bale, not round, like the American bale, and it stretches the fiber. (786, 787.)

Mr. HUTCHINSON, representing the American Cotton Company, testifies that a premium of 45 points is universally allowed in the Memphis market on cotton in round bales, and is guaranteed by the American Cotton Company. This premium is not always maintained at local points where there is a stiff fight to shut out the round bales. Wherever a round-bale press is located it also raises the price of square-bale cotton. The Memphis buyer, in order to get any square-bale cotton at that point, has to telephone his agent raising the limit a quarter or half cent a pound.

Mr. Hutchinson says 50,000 pounds of cotton in round lap bales can be put into a box car and shipped directly to the Eastern mills. It would otherwise require four box cars to carry the same amount of cotton to Memphis, where it would be unloaded, trucked into the compress shed, compressed, and loaded back into the cars, and it would then take two cars to carry it East.

Mr. Hutchinson knows of no objection on the part of foreign spinners to the round bale, and says that he has had applications for these bales from a good many brokers. He says there is no difficulty in sampling. It is not necessary to bore the

CCXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

materials in every bale. Southern mills also have the advantage of longer light during the day, and they work longer hours. (52, 53.)

C. Other crops. (See also *The sugar industries*, X, pp. CCLI to CCLXXIII.)—
1. Potatoes.—*Vermont.*—Mr. SPEAR says Vermont is a very good potato State, but there has been so much difficulty with rust, potato bugs, etc., that farmers have largely confined themselves to what they need for their own use, though the western part of the State sends potatoes to market. All kinds of potatoes are produced. Mr. Spear has seen at a fair 170 kinds produced by one man. (408.)

New York.—Mr. NORRIS says there are certain sections of New York that grow as good potatoes and root crops as are grown anywhere, except sugar beets, which can be grown to greater perfection in California. (328.)

New Jersey.—Mr. MAGIS testifies that potatoes can still be raised to advantage in New Jersey. In Union County they are raised largely for the early market. After the New York potatoes are in a condition to ship they can be sold at prices which make it unprofitable for the raisers in that part of New Jersey. (100.)

Mr. COLES, of Salem County, New Jersey, says a great many early potatoes are grown in that section, 12 and 20 acres of a 100-acre farm being devoted to potatoes each year. The early potato crop is subject to competition from the South. (127.)

Mr. Coles says the potatoes are generally planted with a machine in his section. There are no improved plows, but the cultivator and the gang plow are used to some extent. The potatoes are usually plowed out with a potato plow, though diggers are sometimes used. (128.)

Kentucky.—Mr. NALL testifies that about 20 years ago, when he was a young agricultural editor, he heard of a new system of growing potatoes, and when he investigated it found a couple of Germans growing potatoes earlier than any of their neighbors and superior in appearance, though they were a well-known variety. They planted immature seed potatoes, digging up a part of their potatoes, exposing them to the sun, then putting them in a shady place and cutting them up and planting them in midsummer, about the 1st of August. By the time of frost the tubers would be about one-third grown. They would then be taken up and the next spring cut up and planted again. Mr. Nall advanced the theory that when the seed formed the root was ready to decay, and therefore less vigorous than if taken up and planted before the seed formed; and he predicted that this method would revolutionize the industry, and that seed potatoes would be exported from Kentucky, though thousands of barrels of potatoes were then shipped into that section from Western New York and Michigan. He has lived to see this prediction verified. For many years seed potatoes have been shipped to the North, and are never allowed to get more than one-third of their growth. This discovery made Jefferson County a very large potato-growing county, and the seed goes north from there instead of coming South. A great many potatoes are grown near the cities of Kentucky, the second-crop seed being used; but now the potatoes dug in July are held in cold storage until the next year, and then planted, instead of being planted the same year. (807.)

2. Truck farming.—*New Jersey.*—Mr. COLES, of New Jersey, says that while the Salem County farmers have not abandoned the growing of cereal crops, they are growing them less than formerly, and have turned their attention to other things, such as berries, asparagus, tomatoes, and sweet potatoes. Southern competition has hurt truck farming a good deal. The effect of Southern competition on the New Jersey farm is especially severe when the Southern crops are delayed by cool weather, so that the glut in the market occurs at about the same time the New Jersey products are ready for market. (123, 127.)

Maryland.—Mr. AGER testifies that there is a great deal of truck farming in Maryland, near Washington and Baltimore. It was formerly very profitable, especially if the farmer understood how to maintain the fertility of the land and grow the best crops; but now many complain that they can do no more than make ends meet. Some grow winter crops in greenhouses, and that is quite profitable. (106.)

Mr. Ager says that the importation of early vegetables from the South has a tendency to lower prices of Maryland products. There is generally a steady shipment from the South during the season. Early potatoes from Norfolk are mentioned as an example. Mr. Ager says transportation, especially by boat, from lower Virginia is almost as cheap as hauling 10 miles by wagon. The Maryland gardeners do not send vegetables to the North, but the commission men do so to some extent. (110.)

Mr. WHITNEY says that 15 years ago the truck industry was in a very flourishing condition in Maryland, and in certain localities the people were very prosperous; but with the development of transportation facilities and with the opening up of truck areas in South Carolina and Florida, the industry has been given up in certain parts of Maryland. (860.)

South Carolina.—Mr. HAMMOND, a cotton planter of South Carolina, says that while the regular truck gardens on the seacoast are permanent institutions, the raising of such things as watermelons and canteloupes in his section does not seem to have been very successful. In any case it must be done on a large scale, so that shipments can be made in carloads. (834.)

3. Tobacco.—Connecticut Valley.—Mr. STOCKWELL says there is a considerable tobacco industry in Massachusetts, in the Connecticut Valley, and to a limited extent in the Housatonic Valley. The industry has been thriving since 1897; it was formerly much depressed, there being no sales because of fear of tariff changes. (899.)

Mr. HALE thinks that for the average planter of tobacco in the Connecticut Valley tobacco is probably the best money crop. He has been educated to grow it, and that is about all he knows. The most prosperous are those who have tobacco in connection with dairying and market gardening, but most of the farmers grow tobacco as the only staple crop. (393.)

Sumatra tobacco.—Mr. WHITNEY says that as a result of the soil-survey work of the Department of Agriculture, Sumatra tobacco was recently grown in the Connecticut Valley and brought 71 cents a pound, while the ordinary crop is sold for 20 cents a pound. In the soil survey it appeared that conditions were favorable on a certain soil in the Connecticut Valley for the production of this tobacco, though so far as known there is no other part of the country besides Florida where the industry can be pursued. Mr. Whitney is confident that there is a possibility of producing in this country \$6,000,000 worth of tobacco which is now imported annually from Sumatra. (870.)

Mr. Whitney goes on to say that on the light sandy soils of the Connecticut and Housatonic valleys a fine grade of wrapper leaf tobacco is produced, which can not be grown in Pennsylvania or Maryland. The introduction of the Sumatra tobacco in 1865 has affected the tobacco industry of the Connecticut Valley. Its fine texture has been so appreciated that it has been imported in increasing amounts ever since, in spite of the duty of \$1.85 a pound. Manufacturers prefer paying \$2.50 or \$3 a pound for Sumatra tobacco to paying 18 or 20 cents for the Connecticut leaf, although the quality of the Connecticut leaf is preferred by many. It has seemed to Mr. Whitney that the tobacco industry of the Connecticut Valley was threatened. This country takes the best Sumatra, paying \$1 for the tobacco and \$1.85 as duty, and there is more and more a feeling against the use of the domestic leaf.

Realizing this condition, the Department of Agriculture 2 or 3 years ago inquired into the possibility of raising the Sumatra tobacco in this country, so as to obviate the importation of such large amounts from Sumatra. It was decided to try a particular soil in the Connecticut Valley. Sumatra seed was planted under a cheese-cloth shed, so as to protect the plants from the sun and maintain the quiet and humidity of the air. The tobacco was grown and cured by a combination of the methods used in Florida, Sumatra, and Cuba, and was pronounced by experts to be fully equal to the imported Sumatra leaf. It is confidently expected to establish an industry in the Connecticut Valley which will successfully compete with the Sumatra tobacco, which is now imported to the extent of \$6,000,000 a year, besides duties. Some Sumatra leaf is being grown also in Florida, where the climatic conditions during the growing season are not very different from those of Connecticut. (876.)

Mr. Whitney explains that the cheese-cloth covering is not affected by any ordinary storm. The first cost of the shed is between \$200 and \$500 an acre, depending upon the cost of the lumber. In the South near sawmills it costs about \$200 an acre. The cheese cloth costs about \$100 an acre, and must be renewed each year. The shed will last about 5 years. The covering goes entirely over the field, and has the effect of a great greenhouse, greatly reducing and modifying the sunlight and heat and making the air stagnant and moist. The conditions are really tropical. In the Connecticut Valley the plants grew to the roof—9 feet high—though the ordinary height of tobacco plants is about 4 feet. The cheese cloth does not prevent evaporation, but conserves the moisture so that the crop does not suffer from drouth. It is also a protection against frosts. (877.)

Maryland.—Mr. WHITNEY says that before the war tobacco was grown very generally in Maryland, and since the war it has been grown extensively in the southern counties; but with the introduction of white burley tobacco in Ohio and Kentucky, where a large yield is produced at a comparatively low cost, the tobacco industry in Maryland has been largely given up, with disastrous effect upon the farmers of Maryland. (860.)

Virginia.—Mr. WEDDERBURN says that near Petersburg and Dinwiddie, Va., a fair average yield, on a good piece of land well fertilized and cultivated, would be one-fourth or one-fifth of a pound of shipping tobacco to the hill. (823.)

Kentucky.—Mr. NALL, Commissioner of Agriculture of Kentucky, divides the State

CCXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

into 5 districts according to the character of the soil, and also separating the mountainous from the agricultural part, which latter comprises 3 divisions. Ninety-five per cent of all the dark export tobacco is grown and handled in division No. 1, constituting the western end of the State. Perhaps two-thirds of the red tobacco for domestic manufacture and the greater part of the "regie" tobacco are grown in division No. 2, lying immediately east of No. 1. The export tobacco is long, heavy tobacco, strong and black, and is usually marketed loose in wagon-load lots, and then rehandled and straightened. At least that going to England is stripped, the stem being taken from the leaf to make it lighter, as it pays a duty of 86 cents a pound when taken from the bonded warehouse in England. In the third division is grown about 90 or 95 per cent of all the white burley tobacco, a variety originating across the river in Ohio, and now cultivated throughout the blue-grass region and used almost exclusively for domestic filler and wrapper, as it will absorb a great deal of licorice, moisture, sugar, and other things which are cheaper than tobacco. The black tobacco is cured by fire; the burley tobacco is cured in barns without fire. Very little of the tobacco grown in Kentucky is used for cigar making, though the cultivation of cigar tobacco has been tried unsuccessfully. (806.)

North Carolina.—Mr. WHITE says that in the Durham district and in certain other parts of North Carolina most of the tobacco crop is produced by small croppers, and the landlord or some one else sells it for them. (420.)

Georgia and Florida.—Mr. HALE testifies that Georgia can grow a fine-flavored tobacco for a filler. Some sections of Florida and Georgia, by using Cuban seed, produce the so-called Havana tobacco, which is not as good as the Cuban, but much better than much that is sold as such. With the Connecticut or Sumatra leaf for a wrapper it makes a very fine cigar. Mr. Hale thinks it probably can not be grown if tobacco is brought from Porto Rico and Cuba free of duty. He says the tobacco farmers are very much stirred up about it. (397.)

Bright tobacco.—Mr. WHITNEY says that many areas, formerly of little value, have been developed by the introduction of the bright-tobacco industry, which is adapted only to soils with certain peculiarities, which happen frequently to be unfavorable for general crops. (876.)

Marketing of tobacco.—Mr. WHITE testifies that the farmers of North Carolina send their tobacco to stores and warehouses and have to take whatever price is offered, except those who can hold it in hogheads and ship it when they please to Richmond or Danville. (419.)

Mr. GRAHAM thinks that the price of tobacco has gone down over 50 per cent in 8 or 10 years, while the crop has decreased. He attributes this to a trust or combination of buyers. (435.)

Foreign tobacco monopolies.—Mr. NALL calls attention to the practice of the Italian, Spanish, and perhaps French Governments in appointing an agent or selling to a syndicate the privilege of supplying all the tobaccos that are obtained from America at a certain price. The growers are absolutely at the mercy of these people as to the prices of the export tobaccos, as there is nobody else to sell it to. It can not be shipped to those countries and put in bonded warehouses and sold to manufacturers. The tobacco interests endeavored to get relief in sales in the open market in those countries through a bill introduced in Congress in 1898 by Hon. J. D. Clardy, of Kentucky; but it passed only the lower House. Legislation along that line might result in benefit to Kentucky, Tennessee, Indiana, southern Illinois, and Missouri, all of which grow the export or regie tobacco largely. (810.)

4. *Flax in North Dakota.*—Mr. BUDGE thinks flax is the most profitable crop that has been raised in North Dakota for years. From 10 to 15 bushels are raised to the acre, worth in the fall of 1900, \$1.45 and \$1.60 at the farm. It is thrashed just as wheat is. (852.)

Flax seed and straw.—Mr. PROM, of Milton, N. Dak., says the flax seed is shipped to Minneapolis. The average price in 1900 was from \$1.40 to \$1.50 a bushel. The production varied from 8 or 9 to 24 bushels, averaging 14 and 16 bushels. It is an excellent crop to raise, and is not thought to be hard on the soil if the land is properly treated, or if the crops are rotated. The flax is grown entirely for seed, and the straw is a by-product. Mr. Prom thinks the price of the straw is \$2 a ton, and the yield probably 2 tons to the acre. (793.)

Mr. Prom says sheet-iron drums are filled with flax straw packed as closely as possible, opened at the bottom, and put on top of a cook stove with the lid removed. This makes a good fire, which heats the room very comfortably and lasts a long time. There is a very disagreeable odor, but it is a great saving for farmers who are distant from timber.

Flax straw is also utilized for feeding stock. (788.)

Flax mill, Fargo.—Mr. PROM says there is now in Fargo a flax mill where the seed is

run through rollers and the wooden part taken out. The fiber is then pressed and shipped East for linen manufacture. The business is said to be very profitable, and it is very profitable to the farmers living near by. (792, 793.)

5. *Tea gardens.*—Mr. SHEPARD, of Pinehurst, S. C., testifies that the first tea plant brought to this country was planted about 100 years ago on the Ashley River, about 15 miles from Charleston. During the fifties, Mr. Junius Smith, of Greenville, S. C., made some experiments which attracted considerable attention, and later the United States Government distributed tea seed through the Patent Office and also imported tea plants from China; but the gardens which were established just before the war were abandoned or neglected. About 20 years ago Mr. John Jackson came to this country from India and started a tea plantation in Georgia, which attracted the attention of Commissioner Le Duc, of the Department of Agriculture, who secured Mr. Jackson's services in the establishment of an experimental tea garden; but Mr. Jackson's health broke down, and for lack of an expert the undertaking was abandoned. About 1890 Mr. Shepard purchased a portion of this same plantation and began his experiments at Pinehurst. He wished to produce enough tea to ascertain the cost of production and test the commercial aspect of the question. He has planted between 50 and 60 acres of tea, and looks forward to a production of from 10,000 to 15,000 pounds annually. He has experimented with all the different kinds of tea seed that he could procure either through the trade or through the Departments of State and Agriculture, and under as many different circumstances as possible. He has succeeded in producing tea at the rate of 400 pounds to the acre, with a yearly increase of from 50 to 75 per cent, and sees no reason why it should not be produced at the rate of 600 or even 800 pounds to the acre. In some of the gardens of India and Ceylon tea is produced at the rate of 800 to 1,000 pounds to the acre. The production is a little over one-half ounce to the bush in Japan, and 1 to 2 ounces in China; one of Mr. Shepard's fields has given him $5\frac{1}{2}$ ounces, so he thinks the outlook is favorable. His green tea has been reported by experts as inferior to nothing brought to this country, and it is not artificially colored; but most people do not like it, just as they do not like the best Japanese and Chinese tea. There is very little tea brought to this country that costs more than 20 cents a pound in Japan, though there is a great deal of tea grown in the Orient that costs from \$5 to \$50 a pound. The teas that approach Mr. Shepard's black teas most nearly bring from 30 to 40 cents in bulk in the New York market, or 75 cents to \$1 at retail. Mr. Shepard feels confident of being able to raise tea at a cost of less than 40 cents, even with only 50 or 60 acres, and very much less with larger acreage. He has never had any trouble in selling it above 40 cents a pound, and never carries any over from season to season. The preparation of the field is very expensive, but it is planted for an indefinite future, and the picking extends over half the year. From April to the middle of October the bushes are picked every 10 days, making 20 pickings. If a month or two of the picking is lost by bad weather or accident, there are still 4 or 5 months of picking.

The tea pickers are colored children, who earn from 20 to 50 cents a day. They are very fond of the work, which is extremely easy, consisting simply in pinching off the leaves and putting them in a Swiss trout basket suspended at the waist. It is very much easier than cotton picking, and they can earn much more wages. Mr. Shepard does not consider it profitable for children of less than 8 or 9 years to go into the tea field. He has a free school on the premises, kept open for 9 months in the year, which all the tea pickers must attend. One of his objects was to establish a new industry in a country where thousands of people lack employment and where it was desirable to supply a healthy and easy occupation during the summer, for children and women particularly.

In February, 1899, the thermometer fell to half a degree below zero at Pinehurst, the greatest cold in South Carolina for 150 years, but the tea plants were hardly injured, with the exception of two gardens in a sheltered position and full of sap, which had to be pruned to the ground.

Mr. Shepard says tea from China, Japan, and the Himalayan provinces of India might be cultivated over a large portion of the Southeastern and Gulf regions; those from tropical and subtropical climates over a smaller portion of the country, as a very small part of the country is free from frosts. The soil best adapted to tea raising is rich, level land, with a light, porous, loamy soil, well drained and capable of irrigation. The tea-producing countries have from 50 to 150 inches of rainfall as against 30 inches in South Carolina during the 6 months of the picking season, and Mr. Shepard proposes to supply the deficit by irrigation. A tea garden ought to come into remunerative bearing in 3 or 4 years. On the recommendation of the Secretary of Agriculture, Congress has appropriated a large amount to be devoted to the prosecution of Mr. Shepard's work. (440-443.)

Consumption of tea.—Mr. Shepard states that the consumption of tea in this coun-

COXXX THE INDUSTRIAL COMMISSION:—AGRICULTURE.

try is about 80,000,000 or 90,000,000 pounds a year. The average consumption is only about one-third that of Great Britain and the British colonies, where it ranges from 5 to 7 pounds per capita. In Russia the consumption per capita is about the same as in the United States; the other nations of the world consume, comparatively little tea. (443.)

6. **Fruit growing.**—*Massachusetts.*—Mr. Stockwell says apples are raised to a large extent in Massachusetts, and he thinks very profitably. The apples are of good quality, and are shipped largely to foreign markets. The main apple for shipping is the Baldwin; the foreign market demands a red apple. The Baldwin is raised in Canada, and the Canadian apples stand high in the foreign market. The Northern apple keeps better than the Southern.

Peaches are again being raised in Massachusetts. At one time they were generally cultivated, but the lack of certain elements in the soil and insect enemies and other causes led to the abandonment of the industry. (895, 896.)

New York.—Mr. ROGERS, president of the Binghamton Beet Sugar Company, says almost every variety of fruit except the orange and banana can be grown to perfection in New York State; no apples have a better flavor than New York apples. The soil and climate of New York give a larger variety of fruit than is produced anywhere else on the globe. (552.)

Fruit evaporation in New York.—Mr. NORRIS testifies that the business of evaporating fruit is carried on very extensively in Wayne County, N. Y., and the surrounding country. Some farmers sell out their whole crop to be evaporated; some like to get rid of doing the work, and sell their apples out and out, agreeing to deliver them to the evaporator, or to give the buyer the privilege of barreling a portion of the fruit. It is becoming very customary for the buyers to do the packing, and their packing is more uniform. The evaporated fruit takes the place of fresh fruit at hotels, restaurants, etc., and a great many private families use evaporated apples. The fruit is put up in 50-pound pine cases as a rule; some is put up in 25-pound cases, and in 2 and 5 pound paper packages. The fruit is marketed all over the world. Evaporated fruit kept from the air and in cold storage will keep for a long time. Mr. Norris has known it to keep as long as 4 years and be perfectly good. (322.)

North Dakota.—Mr. BUDGE says North Dakota is not adapted to fruit, except small fruits, crab apples, etc. It is too far north for the Baldwin apple, but a hardy apple is being tried. Fruit is hard to take care of because of the cold. When the farmers set out fruit trees they have to shelter them. The cold is a dry cold, and not as severe as in New England, but it comes earlier in the fall and lasts longer. (848.)

Peaches in Maryland.—Mr. WHITNEY says that the introduction of peach culture in western Maryland has created an industry on soils which were formerly of little or no value and which are now worth up to \$1,000 an acre. The conditions have made it possible to produce a late peach of excellent quality which does not come into competition with those from the Eastern Shore and southern Maryland. These soils are of no value for general farm purposes, but are particularly adapted to the production of late peaches. (877.)

West Virginia.—Mr. CLOHAN, of Martinsburg, W. Va., says (June, 1900) that it is not over 5 years since the planting of fruit trees to any extent was begun in that section of the State. Before that there was only one fruit grower in Berkeley County. His sons are now at the head of all fruit industries in that end of the State. The largest fruit plantation in that part of the State is that of the Allegheny Orchard Company, in Hampshire County, which has about 1,000 acres altogether, of which about 600 acres were bearing in 1900. The company raises peaches exclusively.

Georgia.—Mr. HALE, of Fort Valley, Ga., raises peaches and Japanese plums most largely, and also various kinds of melons, etc. He says the Georgia peaches are very much better quality than those grown anywhere else; they are a little drier than those grown in the North, but richer and sweeter. Northern fruit is more juicy than the Southern varieties, but lacks the maturity and richness of the latter. (377.)

Mr. Hale testifies that the original fruit plantations of Georgia were developed by native men, and that one of the largest places is still owned and managed by a native; but there are a number of Northern people in the business there. A large number of people in Ohio have formed stock companies, and go South for a sort of picnic in the winter and again in the harvesting season. (400.)

Mr. REDDING declares that the possibilities of growing fruit in northern Georgia are unlimited. A market is found all over the North and West, from Boston to St. Paul. Very few apples are grown; there is no Georgia apple that will as a rule compete with Northern and Western apples. (448.)

Alabama.—Mr. POOLE says that fruit industries are being encouraged in Alabama. Fruitdale, near Mobile, shipped about 80 carloads of peaches to Chicago in 1900, and

will ship 200 carloads in 1901. All fruits do well in Alabama, particularly peaches. A grape-growing industry is also developing. There are 2 grape-growing towns, Cullman and Claiborne. Cullman is settled by German immigrants; there is not a negro in the county, and it is one of the most prosperous counties in the State. Farm products of every description are raised there. Claiborne is settled by people from the Northwest and by Scandinavians. They grow grapes on about 6,000 acres, and make several different kinds of very fine wine. (926, 927.)

Oranges in Florida.—Mr. WHITNEY says oranges have been grown in Florida for years with great success, and the industry has flourished in the most promising way until a season of frosts and freezes has thrown the industry back for years and ruined a large number of people. (862.)

California.—Mr. NAFTZGER, president and general manager of the Southern California Fruit Exchange, says the fruit-growing industry of California has grown in the past decad. to very large proportions. The fruit business, including the products of vineyards and vegetable farms, has increased during that time about 400 per cent. About 50,000 carloads of fruit, of which about 5,000 carloads were canned fruit, were exported by rail in 1900, besides about 3,500 carloads of vegetables and probably about 7,500 carloads of wines and brandies. The sea shipments of fruits and nuts amount to about 3,000 carloads. (950.)

Mr. Naftzger testifies that the navel orange was first propagated in California in the early seventies, the first trees being imported by the Department of Agriculture and sent to Riverside to be planted. The business began to assume practical importance in 1884 and 1885. There are also other seedless oranges, and seedless lemons are produced in California to a large extent. (948.)

Mr. Naftzger pronounces the Santa Clara Valley probably the best prune section of California. The best raisin district is the upper San Joaquin Valley. The best pear district is on the Sacramento River, between Sacramento and the bay. The best orange and lemon district is in the southern tier of counties. The interior valleys are better districts for citrus fruits than the seacoast, being freer from the scale and other effects of sea moisture. The California fog produces on citrus fruits a scale, a fungus smut which propagates very rapidly; but when the hot summer comes on it almost entirely clears itself. The citrus fruits grown in the interior valleys also keep firm much better than those from the seacoast.

The deciduous fruit is gathered from May to October; first the cherries, then the peaches and apricots, then the plums, pears, and grapes, the peaches continuing through to September. The drying goes on at the same time. The raisins, which are made from a variety of grapes which are also shipped in limited quantities in the green State, are cured in September and October. The citrus fruits are shipped from November to July chiefly, though some oranges are shipped every month. Lemons are shipped continuously, but chiefly from the first of June to the first of November.

Oranges and lemons are grown in the same orchards. Lemons are slightly more sensitive to cold than oranges, and so the aim is to put them on ground that is as nearly as possible immune from frost. It is not customary to grow any other crops on the ground beneath the fruit trees in the orchards. (952.)

The oranges are perfectly ripe when picked, except that at the beginning of the season some are shipped for the holidays before they are quite ripe. Lemons are shipped regardless of color; they are picked when they are of proper size and sweated down in a cool place before shipment. The apricots, pears, prunes, etc., must be picked in a rather immature state for long shipment. (952.)

Mr. Naftzger goes on to explain that the up-to-date California lemon grower sends his picker into the orchards with a ring from time to time to test the size of the lemons. As soon as they attain the proper size they are removed from the trees, and if the market is strong they are shipped very soon; if the market is weak they are held. They are put into a cool, dry place and are carefully handled.

The November and December lemons in about 6 months are very fine, tender, ripe, full of juice, and of the highest grade. The time of picking the lemons makes but little difference in the quantity of acid, unless the weather gets too cold. The best lemons in California are the November and December goods. The ripe lemons from the tree are not desirable. They are never permitted to get yellow on the tree. (959, 960.)

Mr. TURNBULL says that oranges and lemons are probably the most profitable fruits to raise in California at the present time. They are grown as far north as Redding, 250 miles north of San Francisco. Probably about one-fourth of the State is suitable for growing fruits of any kind. The rest is too rough and mountainous. (984.)

Olive groves.—Mr. TURNBULL says that there are many olive groves in California, and that the manufacture of olive oil is quite an extensive business. The California

CCXXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

oil is reputed to be purer than the foreign article. Mr. Turnbull's belief is that it is not mixed with cotton-seed oil. (987.)

Nuts.—Mr. NAFZGER testifies that about 700 carloads of nuts of about 12 tons each were shipped out of California in 1900. They were chiefly English walnuts, but there were some almonds. The nut industry is growing very rapidly. (951.)

Melons.—Mr. HALE testifies that cantaloupes were never transported long distances until Colorado proved that it could grow a fine melon and ship it to the far East. Georgia followed Colorado's example, and found that it could produce equally good melons and get them two months earlier. This is a new industry much appreciated by the consumers, and likely to grow. (397.)

Mr. Hale says that when the Rocky Ford melons acquired fame in the market, Georgia and Florida melons were labeled "Finest melons, grown from Rocky Ford seed," "Rocky Ford" in large type and "seed" in very small type, giving the impression that they were Rocky Ford melons. Mr. Hale labeled his cantaloupes "Finest Georgia melons," indicating that they came from the grower of Hale's peaches, and sold them in New York for \$4 a crate, while the so-called Rocky Ford melons sold at \$1.50 and \$2. (398.)

Mr. Hale says there is little or no profit in watermelon raising in Georgia; it has been overdone. (387.)

Cost of production and profit in fruit growing.—Mr. HALE, of Georgia, says the cost of production of fruits varies from about \$15 an acre on a large scale to \$25 or \$30 on a small scale. A crate of peaches, including packing, transportation, cartage, and commissions, costs in a Northern market from \$1 to \$1.25 and sells all the way from 50 cents to \$3. On the whole, with proper handling, there is a nice profit. Canned and evaporated fruits can be produced more cheaply in Georgia than anywhere else in America. (397.)

Mr. CLOHAN says that the soil and climate of West Virginia are very favorable to fruit growing, and that those who have gone into it have made more than twice as much money as those engaged in general farming. (596.)

In 1890, according to a statement of the president of the California State board of trade presented by Mr. TURNBULL, dried peaches were sold f. o. b. Red Bluff at 20 cents a pound, and the prices of other fruits were equally high. It was not unusual for orange growers to net \$500 an acre. (988.)

Markets for fruit.—Mr. CLOHAN, of West Virginia, says that the fruit from that section is marketed chiefly in New York, Philadelphia, and other Eastern cities. Occasionally, when there is a failure in the West, it is sent to Chicago and Cleveland. (595.)

Mr. HALE estimates that the consumption of peaches might be doubled by a better and more even distribution. Some markets, such as Philadelphia, Chicago, and New York, are overloaded, while there are towns of 50,000 inhabitants that have not a crate. There is some improvement in distribution, however. (393.)

D. The dairy industry.—1. *Dairying in various localities.*—*Vermont.*—Mr. VAIL says the average Vermont dairyman who makes a business of dairying has from 8 to 10 cows. Some of the larger dairies have about 300 cows. Every dairy farmer in Vermont is also a mixed farmer to a certain extent; the dairy and poultry business have been joined together, and some of the dairymen raise horses and sheep. The tendency from the beginning has been in the direction of great cleanliness and the eradication of anything that would injure milk, both in the pastures and at the barn and house. (413, 414.)

Massachusetts.—Mr. STOCKWELL says the supply of milk for the cities is a large item in the farming life of Massachusetts. This industry is profitable—at least except in those sections which supply the Boston market, where the "milk combine" has caused a great deal of dissatisfaction. The recent "strike" of the Milk Producers' Union was caused by a surplus.

The making of butter in the country towns is also quite profitable; a good article of uniform quality is made and commands prices higher than the market. (895, 896.)

New York.—Mr. POWERS says the dairy industry of the State of New York has been almost ruined by Western competition. The production has increased somewhat, but the profit has vanished. The farmer turns off as much money, but spends more in connection with his farm. Twenty-five years ago the New York dairy farmer bought very little feed; to-day he buys large quantities of shorts and more or less corn from the West. After deducting the cost of these things and of artificial fertilizers, he has a smaller amount left than formerly. (177, 178.)

Mr. FLANDERS, Assistant Commissioner of Agriculture, New York, says that when the State Department of Agriculture was created between 3,000,000 and 4,000,000

40-quart cans were taken into New York City annually over milk routes. In 1900 the amount was between 13,000,000 and 14,000,000 40-quart cans. Formerly it was gathered within a few miles; now it is carried more than 250 miles. Mr. Flanders thinks that these results are due to the securing of purer milk by the enforcement of the State law. (998.)

Mr. NORRIS, master of the New York State Grange, thinks dairying is more costly in New York than in Illinois. Land has not been worth as much an acre in Illinois as in New York, and in certain portions of the West the grasses are as well adapted to dairying as those of the Eastern States, with a few exceptions. There are only a few of the Eastern States in which the grasses are especially adapted to butter and cheese making, and there are portions of the West that excel the East in the manufacture of fine butter. Western dairy products come into sharp competition with the New York product. In certain sections of New York dairying paid better in 1899 than for the previous 10 years, because of the drought and consequent diminished production of milk, which increased the value of the product. (327, 328.)

New Jersey.—Mr. KETCHUM estimates that about half the farmers of Mercer County, N. J., now make a specialty of dairying. Those who live within hauling distance of Trenton market their milk there, and the others ship to Philadelphia. (132, 133.)

Mr. MAGIE, a dairyman of Elizabeth, N. J., says the Ayrshire cattle are very popular in New Jersey; that Jerseys are wanted by those who sell cream; and that Guernseys are a good breed. Full-blooded Jerseys stand the climate of New Jersey well, but it is very hard to get a Jersey herd that will give milk enough to pay. A cow must average 6 or 7 quarts a day the year around in order to pay; an exceptionally good cow will average 10 quarts a day. No beef cattle are raised in the vicinity of Elizabeth, and not one dairyman in a hundred raises enough calves to keep up his own dairy. Sheep are raised in other parts of the State, but not in that vicinity. There are dairymen in the vicinity of Elizabeth who have started with 1 or 2 cows and established a good business. The cattle can be kept on commons about the cities or on farm pastures. But, on the other hand, some men with abundant means who have tried to produce milk for the New York market have abandoned the attempt. The Havemeyer estate had a dairy store in New York City for the sale of gilt-edge milk, but did not realize enough from it to pay the bills, and in 1898 the stock was sold at auction. The price for Jersey milk shipped in ice refrigerator cars and kept on ice was formerly 12 cents a quart, but the price was reduced by competition. (101, 102.)

North Dakota.—Mr. BUDGE says some dairies are now gradually being established in North Dakota, though the winters are so long it is difficult to get enough feed. In the eastern part of the State, where the farmers have been raising wheat, and in the central part, where they are raising flax and mixed crops, they are now raising some cattle. The later immigrants from the older States are raising stock and making butter.

Virginia.—Mr. WEDDERBURN says that from the country between Washington and Leesburg and Manassas thousands of gallons of milk are shipped into Washington every day. There are no creameries; 1 or 2 started in Loudoun County, but he does not think they were successful. He thinks there is an immense future for dairying in that section if the people would come and settle there. Fine dairy land can be obtained almost as cheaply right under the shadow of the Capitol as by going thousands of miles away. (623.)

2. *The marketing of milk.*—Mr. MAGIE, of Elizabeth, N. J., says that the dairy business is carried on at a profit in that section of the State where the dairymen can retail the milk from their own wagons, but that producing milk for New York City in the vicinity of Elizabeth can be done only at a loss, and has been discontinued. The dairymen in the upper parts of the State ship their milk to New York very largely. The farmers in the vicinity of Elizabeth commenced selling milk about 1840. At that time it was shipped to New York. The New Jersey farmers turned from the regular lines of agriculture to dairy farming, because as the means of transportation increased the West could undersell them in grain and other products. The prices of milk are now lower than 12 or 15 years ago, and people demand better milk, put up in better shape. The dairymen now bottle most of their milk. In New Jersey truck farmers are giving up that industry and going into dairying. Towns are growing up, but not as fast as the supply of milk is increasing. Mr. Magie thinks the bottom has been touched in the matter of prices, and that the tendency is now upward. (99, 100.)

Mr. Magie says the dairymen in his vicinity, when they shipped milk to New York, or sold to the shipper, got 2 cents a quart. The retail price in New York is from 5 to 8 cents; 8 cents for bottled milk shipped direct from the farm, 7 cents from the can. The New York middlemen get the benefit of the difference between

the wholesale and retail price. Half a cent a quart or 20 cents a can goes for freight. The middlemen have the milkmen come to Jersey City or to the New York depot where it arrives, load their milk, and deliver it. The peddlers keep their own horses and drivers, and furnish the small retail stores with their milk. In Philadelphia the wholesale man owns the wagons and horses and serves the milk routes. Mr. Magie has heard it said that if an independent milk dealer starts in to get a route in New York, the milk dealers' association puts down prices on that route to drive him out. (100, 102, 103.)

Mr. Magie says the price of milk in Elizabeth is 7 cents a quart delivered. Within a year preceding the date of his testimony (June, 1899) it was 8 cents. Jersey City is largely supplied by dairymen near the city. The milk sold in Newark is shipped in from Morris County to a large extent. The price in Newark is about the same as in Elizabeth. Some milk is sold as low as 4, 5, or 6 cents. (100, 101.)

Mr. KERCHEM testifies that the wholesale price of milk in Trenton, N. J., is 4 cents about 6 months in the year and 3 cents the remaining 6 months. The retail prices are about double the wholesale prices. (132.)

Mr. COLES, of Woodstown, N. J., says the dairymen of his vicinity ship their milk chiefly to the Philadelphia market. Milk is shipped to Philadelphia from a much longer distance than formerly. It is carried 200 miles in refrigerator cars for almost the same price it costs to send it 25 miles. The freight on milk from Salem to Philadelphia is 20 cents for a can of 100 pounds or 40 quarts. Mr. Coles thinks it will be necessary to study cheaper means of producing milk. (123.)

3. Butter making in Vermont.—Mr. VAIL testifies that the dairy industry of Vermont has increased very rapidly during the past 20 or 30 years, and to-day all the improved methods are in use. The dairymen have very largely adopted butter as the leading product and have largely adopted the Jersey cow; there are a good many herds of the thoroughbred.

The old method of separating the cream from the milk was a shallow setting in small pans. This was followed by the large-pan setting in pans 3 feet wide and 10 or 12 feet long, with some system of cooling by cold water. The next development was deep setting in cans; the cream was forced to the top by sudden cooling, giving more complete separation and economy of space. For several years, however, centrifugal separators have been in general use. At first the separating was done at the creameries and the milk returned to the farmer, but that is apparently giving place to a more economical system of separating on the farm and carrying the cream only to the creamery. The skimmed milk is fed to swine and young calves. The separators are used very largely on farms. On the small farm hand power is used; there is also a cheap animal power, with which a sheep or a large dog may be used, that will separate from 300 to 500 pounds of milk in an hour. For larger dairies a horse, bull, or heifer is used. The creameries use steam or water power, or any of the modern engines.

A very small amount of cream is churned fresh, making fresh butter without much flavor; as a rule the cream passes through a process of ripening. The churns used are either a rotary barrel or box or a swing churn without any paddles or floats. The original churn was the up-and-down dash churn, followed by crank churns with various devices of floats and paddles. When the butter is taken out of the churn it is usually washed in clear, cold water until the buttermilk is washed out. There are various kinds of butter workers used to eliminate the surplus water and distribute the salt evenly. The salt heightens the color of the butter a trifle. The artificial coloring of butter is quite general during the winter. The coloring matter is now put up in various forms, mixed with oil that combines readily with butter. Mr. Vail supposes that the basis of the coloring matter is annatto, and understands that it is perfectly harmless in the quantities used when it is properly made, though some of the articles put upon the market have been analyzed and condemned. (411, 412.)

Mr. Vail says the milk should be separated before it becomes cold, and cream is usually carried to the creamery every morning. Sometimes the farmer or his wife or children take it to the creamery, sometimes the farmers along a certain road combine and send a team down, and in some instances creameries have sent out teams to collect the cream. (413.)

Mr. Vail thinks it is probably true that if a man understands butter making he can do better to make up his own butter and put it on the market himself instead of sending his cream to the creamery; but it is easier to carry the cream off and get rid of the labor. (413.)

Mr. Vail says the butter is prepared for the market in several ways. There are family prints, tubs, and firkins. The creameries and dairymen always label the goods with their names. The choice dairies that used to get a dollar for fancy butter

now have difficulty in getting a price much in advance of the general market, because the creameries make so choice an article. (412, 413.)

4. Western butter in the East.—Mr. HAMILTON testifies that Pennsylvania produces about 90,000,000 pounds and consumes about 160,000,000 pounds of butter annually. The Northwest has organized the butter industry better than the East. There are boards of trade, such as the Elgin Board of Trade, which inspect dairy products, and whose stamp gives character to the product; so that in many instances Pennsylvania merchants desiring a steady uniform grade take an Elgin brand. Mr. Hamilton refers to an effort being made (January, 1900) to organize such boards of trade in Pennsylvania, and he thinks that when that is fully inaugurated the merchants will prefer Pennsylvania goods to those that come from other States. (368.)

Mr. AGER says hardly any of the butter the Maryland farmers sell in Washington brings a first-class price; the people send out to Illinois and Iowa and get Elgin creamery butter, whereas if farmers living near the city would make a good article they would command first-class prices. (1157.)

Mr. POWERS says that as soon as the method of shipping in refrigerator cars was developed Western butter was taken to the New York market, and the monopoly of 3 or 4 New York counties and their profit in the butter business vanished. (187.)

Mr. VAIL does not know of any Elgin butter being sold in the State of Vermont, though it has a very high reputation. (415.)

5. Cheese making.—Mr. VAIL testifies that cheese making is quite an industry in some portions of Vermont. One large manufacturer sends all his cheese to one section of Ohio. The local markets of the State take a great deal, and some goes to Canada and is sold as Canadian cheese at a better price than it would bring as American cheese, because the latter has had the reputation of being filled. (414.)

Transportation of milk to cheese factories in Ohio.—Mr. DODGE testifies that in northern Ohio, where milk is the farmers' largest product, contracts are usually let to the lowest bidder to gather up the milk and carry it to the cheese factories. (690, 691.)

E. Other animal industries.—**1. General stock raising.**—*Vermont.*—Mr. SPEAR testifies that Vermont has a good many stock farms, owned by wealthy men for the purpose of developing some line of farm animals. (408.)

New Jersey.—Mr. MAGIE says that in some sections of New Jersey the farmers are producing corn and hay, and raising cattle and sheep for sale, to some extent; a few horses are also being raised. (100.)

Mr. COLES, of Woodstown, N. J., thinks the increased amount of stock kept in his section makes the total value of farm and equipment about equal to what it was during the higher price of land. (126.)

Mr. COLES adds, however, that very few beef cattle have been raised in his section of late. The price for beef cattle on the hoof is from 4 to 4½ cents. Some few hogs and a great many colts are raised in his section. A good average horse is worth from \$60 to \$90. (129.)

North and South Dakota.—Mr. PROM says the more advanced farmers of Cavalier County, N. Dak., are now raising a great deal of stock. The stock they formerly kept for meat was scrub stock and very unprofitable; but now blooded stock is being taken hold of to see if it pays. Shorthorn cattle do quite well. They have to be fed nearly 5 months in the year, but they eat the straw which was formerly burned after thrashing. Each farmer tries to supply himself with horses, but they are not raised for export; a few are imported every year from Minnesota, and Iowa—a profitable business to the horse dealers. Mr. Prom says that wheat raising is easier than stock raising in North Dakota, especially as water is required for stock raising, and the farmers who have no rivers or lakes have to rely on wells, which are inadequate for a large amount of stock. The lack of artesian wells is one of the main reasons why stock is not extensively raised in North Dakota. (792.)

Mr. GREELEY, of South Dakota, says that the farmers of that section have been compelled to turn to stock raising because wheat-growing exhausts the land and the pocketbook, being more subject to climatic changes than stock raising. There is sometimes a little less income from stock raising, but it is constant in spite of dry seasons or hail storms, and the soil improves. (937.)

Mr. Greeley testifies that cattle are increasing faster than sheep in his section of South Dakota. Cattle raising is more profitable than anything else unless it be sheep. (942.)

Kentucky.—Mr. NAIL says Kentucky has always been celebrated for its stock. For many years it has held the record for the fastest horses, the best whisky, and the most tobacco, and once had the largest herds of cattle. In recent years Kentucky has been distanced by the West in cattle raising, but still has some of the finest Shorthorns, Jerseys, Herefords, Polled-Angus, and Holsteins. (807.)

South Carolina.—Mr. YOUNG, of Fairfax, S. C., says that section is not a good

COXXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

stock-raising country, and stock is not raised for the market. He raises bacon for his own family, and keeps some cattle, but finds that he can buy meat from the West more cheaply than he can raise it. He says his section is not a good country for pasturage. Formerly hay was bought from the West, but, as a rule, it is now raised at home. Mr. Youmans also says that he can buy Western horses more cheaply than he can raise them, the prices during the years 1897 to 1899 ranging from \$40 to \$50. (120, 121.)

Mississippi.—Mr. KYLE testifies that the cattle industry is looked after a good deal more than formerly in Mississippi, because cattle are bringing good prices. Jerseys were brought in years ago, and the country is well stocked with them. Recently the farmers have got the idea that they want a larger breed for beef cattle, and Durham cattle are being introduced.

Mr. Kyle says the idea seems to prevail among the people that they can make cotton to buy mules more easily than they can raise mules, but he does not think this idea is correct. He estimates that it costs \$20 to \$25 to raise a mule ready for the plow, and the price is from \$50 to \$100 or \$125 for an extra good mule. (473.)

Tennessee.—Mr. MANSON, of Tennessee, is certain that it is more economical to raise mules than to buy them. Cattle and sheep, he says, are also profitable. He estimates that his meat cost him less than 2 cents a pound in 1899. He turned out about 25 hogs when the acorns began to fall, and did not see them from the 1st of October until about the middle of January, 1900, when they were all fat. (506, 507.)

Arkansas.—Mr. BALCH testifies that the larger portion of Arkansas is adapted to the raising of good stock, but the people have not paid much attention to it, except in the northern part of the State. Cotton raising and stock raising do not go very well together. There is an increasing tendency among planters in the southern part of the State to raise mules. Mr. Balch has tried to convince the people that they could raise their mules without any expense by making the mares earn their living at the plow. (497.)

California.—Mr. NAFTZGER testifies that the stock interests of California, including cattle, sheep, and horses, are quite large. The wool product of the year 1900 was estimated at 27,500,000 pounds. (950.)

2. Horse breeding.—Professor DAVENPORT testifies that the whole method of breeding horses has been changed within a few years under the pressure of the Chicago market, principally through the efforts of Mr. Berry, to meet the demand of European and American horse buyers. Men are now systematically breeding the classes of horses that are called for in the market. A few years ago, when the horse market went to pieces, the country was full of unclassed horses. It was thought that trotting blood would be a good thing in horses of all descriptions, but it often resulted in crossness or foolishness. Heavy draft horses can be modified by breeding, probably more than most people realize. Professor Davenport thinks the systematic breeding of horses, cattle, and hogs ought to be encouraged. (270, 271.)

Mr. NALL says an American breed of horses is being established in Kentucky—a saddle horse. Nearly all the States have taken them and now have herds of them. It is a resurrection of the old blue-grass saddle horse that was famous during the forties and fifties, but almost disappeared during the trotting fever. Nearly 4,000 of them are now registered. Mr. Nall describes the characteristics of the American saddle horse at some length. He says these horses have been in demand all over the country since they were exhibited at the World's Fair, and some have been exported. Missouri and Illinois have taken leading parts in the development of this horse.

Good specimens sell for from \$500 to \$3,000, and the best specimens are usually bought and trained by professional trainers, after being shown at the county fairs. A great many young farmers give their colts some preliminary training. Mr. Nall says these horses are excellent for family horses and for pleasure driving.

A few coach stallions have been introduced of late, but more trotting horses are raised. Mr. Nall thinks the Kentucky horses compare favorably with any in the world; he thinks the blue grass and the water and soil tend to the best development of the race horse. There are hundreds of stock farms devoted to the raising of horses, and the industry is more or less carried on on nearly all of the farms through the better part of the country, though Mr. Nall thinks that most of the small farms lose money by it. (807-809.)

3. Sheep husbandry.—*New England.*—Mr. GREELEY testifies that some of the worn-out lands of New England are being successfully stocked with sheep. (942.)

Mr. SPEAR estimates that the sheep industry in Vermont is probably not more than one-fourth as extensive as 40 years ago. During the free-wool period the flocks were largely slaughtered. Since the duty upon wool has been restored there has been something of an increase. The present tariff is fairly satisfactory. Mr. Spear says nearly all the farms in the State are adapted to sheep husbandry better than to any

other industry ever practiced by Vermont farmers, and that if the sheep industry had remained prosperous there would not be so many \$5 an acre farms. Many of these farms were too remote for dairying, and there was no good use to put them to.

Mr. Spear says the breeding of Merinos has been a great industry in Vermont in the past, and is still of some importance. Most of the Merino sheep are marketed in Australia, southern Africa, and Argentina. There has been a very great improvement in the Merino sheep since they were first introduced into Vermont early in the century. A good Merino ram yields 20 to 25 pounds of unwashed wool, and there are records up to 40 pounds. The maximum of those first imported was about 10 to 12 pounds. (410, 411.)

Mr. VAIL confirms the statement that there has been a great decrease in the number of sheep in Vermont, but he thinks that at the present time the sheep industry is feeling encouraged; there are better prices for mutton and wool. (415.)

Mr. STOCKWELL says there is very little sheep husbandry in Massachusetts at present; but he hopes the industry is being revived. The State Board of Agriculture is doing what it can to encourage the return of the sheep. In former days sheep were considered a necessary part of every farmer's outfit. Mr. Stockwell says, however, that he has seen too much of the injury to flocks of sheep by dogs to advocate sheep husbandry very strongly under present conditions. The State pays the farmer for the sheep so destroyed, but when one sheep is destroyed the entire flock is demoralized, and the amount of damage is not known. Mr. Stockwell once went to see a farmer whose sheep had been mutilated by dogs, and had him paid liberally; but going back 6 months later he saw that he had not been half remunerated, because of the number of sheep that had produced no young, and the quality of the young, showing the after effect of the fright. One lamb had nearly the appearance and bark of a dog. The dogs so frequently worried the sheep on that farm that there are no sheep there now. There is no effectual legal barrier against dogs. Sheep husbandry involves wire fences and constant watchfulness. Any suggestion that farmers make with reference to the protection of their sheep from dogs is badly received by dog owners. "The dog in Massachusetts is supreme." (899.)

Ohio.—Mr. MILLER says that there are not as many sheep kept in Ohio as there were a decade or two ago, because of the depressed condition of the industry. The industry is now improving (1900), but there has not been time to increase the flocks to the numbers they contained 10 years ago. The industry was affected by tariff legislation. With present conditions Mr. Miller knows no good reason why Ohio may not have as many sheep as formerly. The matter of making sheep raising an independent industry is affected by the high price of lands, but all farmers can better afford to keep a reasonable number of sheep than not to keep them. (619.)

North and South Dakota.—Mr. GREELEY, of South Dakota, says sheep are raised nowadays for mutton. Very few wool sheep are raised in that part of the country now, but the sheep raisers take what wool they can get. As a rule, the farmers have some of the dark-faced mutton breeds crossed with the average Western sheep, yielding about 7 pounds of coarse wool; finer wools are grown on the ranges. With the right kind of sheep and the right management, it is possible to make a pound of mutton as cheaply as a pound of beef, without considering the wool. Mr. Greeley thinks that with cheap lands, the tariff on wool could be dispensed with and the sheep industry still be profitable, but he would not affirm this for the whole of the country or even the whole of South Dakota. There is not very much protection against dogs in South Dakota, and they have demoralized the flocks to some extent, and in some sections have driven the industry out. The dog laws are changed nearly every 2 years, but they do not work well; it is so complicated and difficult to adjust the claims that the law is almost a dead letter. Mr. Greeley declares the dogs an unmitigated curse. (936.)

Mr. Greeley has for years made a specialty of sheep and poultry, and finds the choring on his farm greatly simplified. There is little hired help required, and no large investment is required at the start; while the income is constant. (937.)

Mr. PROM, of Milton, N. Dak., says the sheep industry is not flourishing now in that section. When wool went down to 5 or 6 cents a pound, it was no longer profitable; but it has been taken up again. The cool climate is very favorable to sheep raising; the wool grows long, and the few men that have sheep receive great profit. (792.)

Mr. BUDGE says sheep do very well in North Dakota, and the sheep industry is improving. About 10 years ago the industry diminished. Wool went down, and the farmers of the eastern part of the State, who had a great many sheep, quit the business, but they are now resuming it, and the industry is profitable.

Effect of the tariff on wool. (See also XIX A, p. CCLXXX.)—Mr. GREELEY says "many of our people believe that it is necessary to have a tariff put on wool before

CCXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

sheep will pay, and will come to me and offer \$4, \$5, or \$6 for sheep with a tariff on that they would not pay \$2 for if there were no tariff.' They slaughter the flocks when the tariff is reduced so fast that the market for mutton is ruined; then, when a tariff is put on, they rush back into the business until they overdo it. Thus, indirectly, the tariff has been the cause of harm to the sheep raisers, though a moderate, permanent tariff would help them. During the free-wool period the flocks and the profits of the sheep growers diminished greatly. They could have stood the low price of wool, but when mutton went down, too, and they could sell neither mutton nor wool, they suffered unnecessarily. They are now getting better prices for mutton, on the average. One good result of free wool was that when sheep were sold so cheaply that everybody ate mutton, the public acquired a taste for mutton which it still retains. After the enactment of the Dingley tariff there was a material increase in the flocks and a fair price in both mutton and wool, but at the time of Mr. Greeley's testimony (April, 1901) wool was 5 cents lower than the year before, with no change in the tariff. Mr. Greeley thinks too much dependence was put upon the tariff, that enormous quantities of wool were bought at a higher figure than the situation warranted with the expectation of getting big prices, and that this was being thrown on the market and depressing prices. He adds, however, that the flocks have been increased somewhat, and also that wool is lower all over the world. The amount of wool imported during the year 1899-1900 was a good deal less than formerly.

Mr. Greeley says there is not a sheepman in South Dakota but prefers to have the tariff on wool. Mr. Greeley agrees with the others that the price of wool is better than it would be without the tariff, but he looks for the reaction which has always followed so certainly. He thinks the agitation of the matter does the sheep raisers harm in the long run, the uncertainty hurts the business so. This same reaction, he says, comes to overencouraged mill and factory building. He thinks there will be no material reaction in wool unless the tariff is reduced, but says there is going to be a little reaction from the high prices paid largely by speculators who bought too much. Mr. Greeley predicts that wool will go still lower than at the date of his testimony. He believes, with other wool experts, that it will be more than 20 years before this country will grow the wool it consumes. Mr. Greeley says the uncertainties of the tariff are the greatest drawback, and nearly or quite offset all the advantages of a tariff. (941-943.)

Mr. Greeley testifies that just before the tariff was again put on wool the sheep business in Kansas, southern Nebraska, and Colorado was thoroughly demoralized. (942.)

4. Forage crops.—*Vermont.*—Mr. VAIL says the common pasture grass of Vermont is closely allied with Kentucky blue grass. Of late years it has had to be supplemented with the principal forage crops—clover, corn, oats, and pease. Mr. Vail's impression is that the best dairy work is done among the hills of the State, in the upland meadows. (413.)

Silos in Vermont.—Mr. VAIL testifies that the silo has been very largely adopted by the dairymen of Vermont to preserve the corn crop. The silo is described as a process of canning on a large scale. A large air-tight or nearly air-tight wooden vat is made adjacent to the stable, with a diameter, perhaps, of 16 to 20 feet, and usually 25 or 30 feet high. The corn is brought to the silo and cut in a machine, and the carrier takes it up and deposits it in the silo. The practice advocated by the experiment station is to let the corn mature. For cows it is put into the silo with the ears on, though occasionally a few hundred bushels are thrown aside for the horses, hogs, and poultry. The corn settles down very compactly, pressing the air out; then a few inches of the top decay, making a complete sealing, and the corn will keep any length of time. It turns sour, a portion of the starch changing to vinegar, but the loss is said to be less than in drying. The cows are fed ensilage in connection with hay. The average ration of a Jersey dairy cow is probably half a bushel at a feed; some give much heavier rations. Clover and grain feed are ordinarily used where there is a winter dairy. (414.)

New Jersey.—Mr. COLES, of Salem County, N. J., testifies that the farmers of that section make an effort to raise all the feed required for their dairy cattle, except a certain amount of wheat bran. Some use cotton-seed meal to a small extent, but it has been thought by some that the stock was injured by it. Some ruta-baga turnips and sugar beets are also grown. In the winter, ensilage is used. (131, 132.)

Hay in Virginia.—Mr. WEDDERBURN says that some 12 or 15 years ago the land around Bristow and Nokesville, Va., was valueless; but Northern settlers from Iowa, New York, Ohio, and elsewhere came in and began raising grass, and now, instead of buying hay, they ship hundreds of tons, and the land has increased largely in value. (623.)

Soy bean and clover in Kentucky.—Mr. NALL says the soy bean is not commonly

used as human food, having a ranker taste than most people like; but it is very fine for stock. It is sown after the last plowing of corn. After the plant grows up the hogs are turned in and eat it. It is also cut for hay, and the right variety makes a fine hay for cattle and horses. It is also turned under to enrich the soil, being a great gatherer of nitrogen. It loosens up the soil, and is said to be equal to clover. The red clover has no superior, but it will not grow in Kentucky any more; it is claimed that a little maggot gets into the root and kills it. There is no enemy to the soy bean, however, and it is a rank grower. Some of the varieties grow so rank that they can not be cut or turned under; there is too much of them. (812.)

Hay in Georgia.—Mr. HALE says hay can be produced in Georgia at from \$6 to \$8 a ton, and is worth from \$15 to \$20 in the home market. (397.)

Grasses and sorghum in Louisiana.—Dr. STUBBS says Louisiana is a good grazing country for certain kinds of grasses; "with Bermuda as the foundation for pasture grass it is magnificent." The Northern grasses will grow there in the winter. The Bermuda grasses last from April until November, and from November until April the stock is carried through in the swamps on the grasses not killed by the winter. If they do not prosper they are allowed to graze on the green cane.

Dr. Stubbs says the Bermuda grass will probably carry more cattle to the acre than any other grass in the world. It has stolons running under ground, and will stand biting right into the ground; and for that reason stock raising has been very successfully carried on. There are a great number of bottoms growing various grasses, and the whole State is very well watered by numerous springs. Dr. Stubbs calls it "a little farmers' paradise, almost." Hay is made for home consumption; but very little is sold, because everyone raises his own.

Dr. Stubbs says the *Paspalum dilatatum* is a grass which remains green in Louisiana throughout the season and furnishes grazing even when snow is on the ground. It is being sold in the North as Louisiana grass. (781.)

Dr. Stubbs says the milking cows on Louisiana farms are brought up to the barn and looked after at night; but there is no necessity for this where the cattle are raised in large numbers, as they are in some parts of the State. (782.)

Dr. Stubbs says large quantities of sorghum are raised in Louisiana for stock feeding. The Louisiana sorghum has the faculty of suckering 3 or 4 times a year, so that the 3 or 4 crops a year make a very valuable feed for the mules and stock. (775.)

Alfalfa in California.—Mr. NAFITZGER says alfalfa is grown in some sections of California, particularly for cattle. It will not produce more than 2 or 3 crops a year without irrigation, but with it will produce a crop a month during the season. Well-watered alfalfa will produce 1½ to 2½ tons at one cutting, and can be cut from 7 to 9 times a year. (966.)

F. Diversification and specialization.—1. **The single-crop system of the South.**—Mr. HAMMOND, a South Carolina cotton planter, says that in the old days almost all the agricultural implements were made on the plantation, the work animals were raised there, and almost all supplies were produced there. Now, fertilizers, implements, and work animals are bought, and Western meat, Western hominy, Western meal, and canned vegetables and fruits are supplied by the country stores. Life in the country is more luxurious than it used to be. Things which used to be rare are commonly consumed. But gardens and orchards and such helps are neglected, and the whole attention is given to raising crops for sale. Mr. Hammond regards the change as unfortunate. (820, 821.)

Mr. WEDDERBURN says all the Southern States import wheat and corn. (626.)

For many years, Mr. STEVENS says, the people of Georgia have been "wild and crazy on cotton." They thought everything they needed could be bought more cheaply than they could raise it, but they are just now waking up to the fact that they were mistaken, and for 2 or 3 years they have been raising their own food supplies. At present, Western beef, by its superior quality, holds the field in Georgia, even in the smaller towns, but with proper attention given the matter by the farmers a meat supply sufficient for the needs of the State could be produced. (917, 918.)

Mr. POOLE says that, unfortunately, the farmers of Alabama have grown cotton too exclusively and brought their provisions from the West; but that condition is growing less apparent every year. (925.)

Mr. BALCH has never heard any satisfactory reason for the single-crop system of the South, except that the farmers conceive that with their system of labor it pays better to grow cotton and to buy corn. The large planters rarely try to raise any meat. It is the smaller farmer, as a rule, who raises his meat and bread. Mr. Balch says the men who raise their own grain and meat are the most prosperous. (496.)

Mr. NUNNALLY, of Georgia, declares that cultivation of cotton to the exclusion of grain and live stock is a stupendous error that requires heroic treatment before the mischief can be counteracted. (455.)

2. Diversification of crops recommended.—Dr. WILEY says a single agricultural industry does not stand well alone anywhere in the world; it is necessary to diversify agriculture. (654.)

Mr. BRIGHAM says that the National Grange is endeavoring to educate farmers to diversify their products more largely. The feeding of grain to stock and the improvement of the character of such stock would prove advantageous. It would be possible for this country to produce all the sugar it consumes from beets. The diversification of crops is especially desirable in the South, but the farmers there are difficult to educate up to the need of it. (21, 22.)

Professor BAILEY, of Cornell University, says that while there is often an overproduction in staple articles there is seldom an overproduction in luxuries. The danger of overproduction is one that exists in every business, and in the long run the question will solve itself by the operation of the law of supply and demand. The solution will no doubt come the quicker the freer a crop is from speculation. (1011, 1012.)

Mr. WIETING, Commissioner of Agriculture of New York, thinks that the New York farmer must find his salvation in turning from such staple crops as cereals to those perishable products which do not so well bear transportation—such as fruits, vegetables, and dairy and meat products. The authorities of the State of New York are doing what they can by disseminating among the farmers such instruction as will help them to produce these crops. (994.)

Mr. COLES believes that diversified farming increases the chances of success in New Jersey as well as nearly everywhere else. If the season is unfavorable for one crop another will succeed. (127.)

Mr. HALE testifies that the Georgia Commissioner of Agriculture has for some years been strongly impressing upon the people by his monthly bulletin the desirability of diversification, but it seems to need a practical demonstration. There is, however, a steady improvement in that direction. (394.)

Mr. Hale declares the only hope of agricultural salvation in the South is diversity of agriculture. He does not think there is enough study of market conditions among the agriculturists of the South, especially of the home markets. Georgia buys hay, corn, meat, canned goods, dried fruit, etc., which can be profitably produced at home. Mr. Hale has never known outside hay to be sold below \$16 a ton, and the price of corn is the same as in the high-priced Northeastern markets. Thousands of dollars' worth of dairy products are taken South from the North, which, taking freight into consideration, can be produced as cheaply in the South. Mr. Hale raises natural crab-grass hay which, judging from results, is as good as the timothy and clover hay of the North. Bermuda grass grows in the bottom lands in certain places. Johnson grass, a species of sorghum, will make two or three excellent crops of hay in a year. A gentleman on the Savannah River makes a profit of about \$7,000 annually on 100 acres of Johnson grass, without replanting. It would probably not succeed on very dry land. Hardly enough corn is grown in the South to supply the plantations, though some planters have been raising corn on account of the low price of cotton. Good cultivation would double the crop. Mr. Hale has produced 3,300 bushels of corn on 80 acres, or about 40 bushels to the acre, and sold it at 70 cents a bushel to his neighbors, who were selling 7-cent cotton. (390, 391, 393, 394.)

3. Progress of diversification.—*New England.*—Mr. STOCKWELL, of Massachusetts, says that competition with the West in the grain staples led for a while to loss and hardship, as the West has suffered by the competition of Russia and India, but to-day New England has found other channels of industry more profitable and better adapted to her soil, markets, and people. Fruits are grown in January in greenhouses more profitably than in their season, and the people are supplied with every luxury by New England enterprise. The agriculture of Massachusetts is much diversified by market gardening, truck farming, and the selling of truck direct from producer to consumer in the larger villages and cities. The old lines are followed largely in some parts of the State, however, as in the Berkshire hills, where there is no such market. (895, 905.)

New York.—Mr. NORRIS, ofodus, Wayne County, N. Y., says diversified farming is fast becoming the ruling thing in his section, fruit especially taking the place of other products. Crops such as small fruits, beans, etc., are taking the place of wheat and barley. (327, 328.)

Ohio.—Mr. MILLER says that mixed husbandry is more general than specialized agriculture in Ohio. He thinks it safer for the average man, though the specialist would better go into special lines. (619.)

The Northwest.—Mr. GEORGE says that the farmers of the Northwest, who until recently devoted their farms almost entirely to cereals, are now practicing rotation and diversification, which increase their crops, and are making very favorable progress. (221.)

Mr. HANLEY says it has been found that diversified farming is absolutely necessary in a great part of the Northwest. It is found more profitable to convert a crop into stock, dairy products, etc., than to market it as a crop. (281.)

Mr. MORAN, of Graceville, Minn., testifies that the farmers of his section are compelled to diversify their crops because wheat does not pay, its value apparently having depreciated. The farmers are therefore beginning to seed down with timothy and clover and raise more stock and corn than formerly; contrary to a belief formerly prevailing, a very fair crop of corn can be raised in that part of the country. (708.)

Mr. BUDGE says the farmers of North Dakota are now diversifying to some extent. They are raising some stock, hogs, chickens, and turkeys. Some of them are raising a little flax. There is no market for vegetables, and the rates are so high it is impracticable to ship them away. A little corn is raised for the stock, and a great many of the people have butter to sell. Hay and forage are cheap except in the western part of the State. A few horses are being raised, but not quite enough for the country.

Mr. BUDGE testifies that in the western part of North Dakota considerable attention is given to cattle and sheep. Large ranching is giving way to a greater number of small ranches, and settlers are rapidly getting stock on their own farms. In localities subject to occasional dry seasons flax culture is being successfully started, and several oil mills have been established. The rich sandy soils of the central portion of the State are well adapted to sugar-beet growing, and movements are on foot to establish sugar factories. The introduction of sugar-beet culture has given the farmer another profitable crop, and at the same time supplies in the pulp a good feed for cattle. Two years ago it was thought that corn could not be raised in North Dakota, and so the pork industry has not been started there, but little by little the farmers have planted corn, saved the seed, and replanted, until the better varieties have become acclimated and with proper care are doing very well; so that there is every reason to believe that North Dakota will soon multiply its pork production many times. Thus the diversification of crops and industries, which has been the great need of North Dakota, is rapidly being accomplished. With it will come an improvement in the financial condition of the farmer and the merchant, and the great transportation companies will also profit by it, since it will insure more uniform shipments, not only from year to year, but during the year. One important industry which has just started is the mining of lignite coal. (845.)

Mr. PROM, of Cavalier County, N. Dak., says that county is just in the beginning of diversified farming. The farmers have hitherto been exclusively grain growers, but now are turning to flax, and the more advanced farmers are raising a great deal of stock. (792.)

Mr. JUMER says there has been much tendency toward diversification of crops in South Dakota during the past 10 years. Besides wheat, the farmer raises oats and barley for his own use, and corn to sell. In the southern part of the State the farmers raise a great deal of corn to sell, and have poultry and valuable cattle. (732, 733.)

Georgia.—Mr. STEVENS says the people of Georgia have been trying to raise their home supplies, so that they would not be forced to throw all their cotton on the market at one time. The production of grain has not yet been sufficient to meet the home demand, but this is more nearly possible now than for the last 40 years. Farm products of all kinds meet with ready sale in home markets, with generally remunerative prices. (915, 916.)

Mr. REDDING testifies that the farmers of Georgia generally raise part of their supplies. There has been a great improvement in that respect. There are very few who would not like to raise a large part of their cereals, but many of them make short calculations and do not plant enough. (444.)

In the section of Georgia where Mr. BARRETT lives, near Augusta, the general practice is to raise about 20 acres of cotton to 15 of corn and 5 of other crops. Corn is raised for home use, and is hardly a commercial article. The raising of cotton is not profitable (June, 1899). Horses, mules, cattle, and hogs can be raised cheaper than in the North and West, because there are no long winters; yet the farmers of Georgia do not raise enough mules for their own use. High authorities declare that Georgia is a better State for cattle, milk, and butter than the Northern States. Yet Mr. Barrett believes that the South will never be prosperous on account of the incompetence of negro labor. (56-58.)

Mr. HALE says there is considerable change going on in Georgia from cotton to fruits and vegetables of various kinds, and the more of it the better. This has increased the value of the product from 200 to 1,000 per cent. The profits are all the way from nothing up to 10 times the profit on cotton (the rainfall is a little precarious), but the average is good. These crops require more skilled labor and afford

higher wages. Melons and other fruit give the railroads 15 times as much tonnage to the acre as cotton, and at a higher price per ton. (390.)

Mr. Hale adds that there is an overproduction of cotton, and that there perhaps would have been an overproduction of peaches if it had not been for the freeze. The high prices tempted too many to go into peach raising. In nearly everything else there is an underproduction in the South. (393.)

Alabama.—Mr. POOLE testifies that after the increase in the price of cotton following the war every farmer in Alabama went into raising cotton, thinking it more profitable than other products, and neglected pork and corn; but the decrease in the price of cotton has forced them back to raising more corn, and the State is now raising nearly all it consumes. Mr. Poole says the farmers of Alabama ought to raise all the pork and corn they consume, but they are cotton crazy. The soil is adapted to the cultivation of corn, and Mr. Poole estimates that the yield would average 15 or 20 bushels. In some cases as much as 40 or 50 bushels to the acre are raised in the Black Belt. All crops can be raised in Alabama, and the State Department of Agriculture is encouraging the diversification of agriculture. (920.)

Mr. DILLINGHAM has found by careful questioning of the colored farmers of Lowndes County, Ala., that they are not only planning for plenty of cotton, but also planning to raise food as never before, running in debt as little as possible and learning to save. (166.)

Other Southern States.—Dr. STUBBS says there is now a very prosperous condition of agriculture all through the Southern States. Everywhere there has been a constant tendency toward diversification, the raising of home supplies, increased stock raising, pasturage, and forage crops ever since cotton reached its low mark. The unexpectedly high price of cotton will probably in the end be something of a detriment to this progress, because the people will begin raising it more extensively; but the increased price, together with the home production of other articles, has put the people in excellent condition all through the South. Dr. Stubbs believes it desirable to persuade the farmers not to plant too much cotton, but to maintain diversification, because cotton can not remain at 10 cents; the area to be devoted to it can be increased or decreased to any extent. (785.)

4. Diversification of agriculture difficult in the Southern States.—Mr. BROWN believes that the lack of prosperity in Georgia and other Southern States is largely due to the almost entire confinement of agriculture to raising cotton. The reason for this practice is that cotton is the only crop on which money can be borrowed, and which is certain of a market. Corn, for example, is used only for local consumption, and there is no sale for it immediately after harvest; hence it can not be used to pay notes. In the early days nothing was salable except cotton, and the price was high. Farmers supposed that by increasing their output they would increase their profits. But as means were discovered for producing more cotton at the same cost, the price went down excessively from 20 to 4 cents. Meantime, farmers having gotten into the rut of planting cotton only, found it difficult to start in any other line. Their labor is trained to raising cotton. To start in any other crop requires an investment in advance, and it is impossible to borrow on the prospect of any crop except cotton. Moreover, the country is not specially adapted to raising cereals or food crops or cattle. These articles can not be sold at competition with the West. Nevertheless the witness believes that the only salvation of the Southern farmer is by diversification. He must raise a large variety of articles for his own use instead of buying them. This is much more likely to succeed than speculative farming. The witness has found diversification advantageous on his own lands. (60, 61, 64, 70.)

The witness states further that the reason why the South can not compete with the North and West in raising any particular crop (except cotton) for sale in the market, or in stock raising, is that the soil is after all somewhat inferior, and that the heat of summer dries up the grass and interferes with cattle raising. But a very wide variety of products can be raised, making it possible for the farmer to supply his own needs almost altogether. The rotation of crops, or the alternate use of land for grazing and for crops, is beneficial. The witness deprecates the fact that a good deal of corn is imported into Georgia, believing it to be unnecessary.

At the same time, the diversification of manufacture in the South would be of the greatest advantage. Each locality should manufacture a variety of products, largely supplying its own needs. In this way local markets for agricultural products would be established, and conversely a local market for manufactured products. This change in method would save the profits which are made by middlemen, or at least would prevent them from going out of the State. The Southern States are able to offer great advantages to capitalists, especially for cotton factories, in the way of cheap labor, buildings, etc. The witness knows of no disposition on the part of the people of Georgia to antagonize capital and hamper business by legislation. What-

ever legislation can be devised for encouraging manufacturing should be enacted, but the witness makes no definite suggestion. Some municipalities already exempt factories from taxation. (64, 68, 73.)

Mr. LOVEJOY confirms the testimony of Mr. Brown as to the difficulty of beginning the diversification of crops. The exclusive production of cotton was begun at a time when it was very profitable, and then and now it is the only crop for which there is a certain market and on which money can always be borrowed. Moreover, it can be more satisfactorily raised by negro labor than other crops. It will wait, if necessary, while work on the other crops must be done at the particular time when needed.

Diversification is desirable, but must be begun by degrees. Furthermore, the soil in Georgia is not specially adapted to other crops. It will raise only from 10 to 15 bushels of corn per acre, from 5 to 10 bushels of wheat, and from 1 to 2 tons of hay. (76, 78.)

Mr. HAMMOND, a cotton planter of South Carolina, says that everyone there, from the banker to the most unskilled field hand, is ready to promote the industry of cotton growing. Anybody that starts at cotton planting for the first time will find everything fitted to help him. The case is different if he undertakes the culture of any other crop. He will have to search for instructions and try experiments; and experiments are costly. But diversification is what the region needs; especially stock raising. For this industry the meal and hulls from the cotton-seed oil mills, the heavy crops of ensilage that are made from the Southern varieties of corn, cow peas, Bermuda and Johnson grass offer special facilities. (830.)

Mr. GRAHAM, of Machpelah, N. C., says a great many farmers in that section have bought homes in the last 20 years, and consequently are in debt, and have to raise cotton for the credit. Ten acres of cotton afford more credit than 50 acres of corn. He has seldom known mortgages to be taken on corn crops. Cotton can always be sold, but the selling of wheat or corn will sometimes be doubtful. (436.)

Mr. YOUNG, of South Carolina, says he has raised watermelons, corn, vegetables, and other crops, but after mature consideration as to whether there was any crop he could plant with a certainty of reaping a profit, he decided that the best promise for 1899 would be in cotton, although he had tried it the year before and lost money on it. His section does not produce wheat. An experiment with wheat was made there in the spring of 1899 which was not very satisfactory. It is cheaper to raise cotton than wheat. (117, 118.)

Mr. Youmans adds that some years he can make money on watermelons, but at other times they are a dead loss. South Carolina farmers have tried watermelons, potatoes, and wheat. He knows a man who lost a great deal of money on a vegetable farm, and another who lost thousands on tobacco. Mr. Youmans raises all his home supplies, such as oats, corn, and forage, but as a money crop he thinks cotton is the best available. (119.)

Mr. PEEK, of Georgia, testifies that somebody is always ready to buy cotton at some price, and a market can be found near at hand. (461.)

5. Practicability of diversification in the South.—Mr. MASON, an ex-slave, testifies that he has always been able to make his living independently of cotton. His custom is to put about half his crop in corn. His former master, who rented to him after the war, advised him that bread and meat could be bought cheaper than it could be raised, but after 10 years acknowledged the other plan better. Mr. Mason finds that corn is the strength of the farm; it strengthens the stock, fattens the pigs, and improves the ground. He says, however, that young men should not engage in mixed farming unless they have a knowledge of plants. (500, 501.)

Mr. BARRITT, a large farmer of Georgia, has not been able to make money through a diversification of crops, although he has been able to keep his land from being mortgaged. He has raised truck, horses, cows, and hogs. The watermelon industry in Georgia has been entirely destroyed by the high freight rates to the markets. The nearer to the farm the goods can be sold the better off the farmer is. (49-51.)

6. Dependence of diversification upon local markets.—Dr. CROWELL says the chances for diversity increase with nearness to a city. (334.)

7. The tendency toward specialization.—Mr. GREELEY, of South Dakota, concedes that diversification is an important factor in agriculture, yet he does not see why farming should be an exception to the tendency of business to specialize. He finds that as a rule the farmers who are making a specialty of some line, bringing others in incidentally, studying their own tastes, markets, soils, etc., and growing something to which they are particularly adapted and mastering that line of farming, are getting ahead; that they have more leisure, and that their sons are more apt to go into farming. Specializing eliminates to a great extent the objection so many young men and women have to farming—the confinement and drudgery of it. Mr. Greeley thinks, from what he has seen of the best farmers in Minnesota and the Dakotas, that the

best part of the advanced agriculture is the tendency to specialize, but adds that it is dangerous to advocate that kind of farming too much with the inexperienced. Raising wheat exclusively he does not consider farming. (937.)

Mr. WHITNEY pleads for the cultivation of the particular crop or crops the land is best suited to. He is convinced that the future for the New England States as for the Southern States, is in the direction of specialization. They are peculiarly fitted for certain special industries, and the markets are close at hand. All thought of competing with the general farm crops must be given up, and the farmers must look forward to building up certain industries which the conditions make it possible to develop. In many cases very important industries have already been created in the New England States, notably the tobacco interests of the Connecticut Valley, the truck and greenhouse interests along the sound and around Providence and Boston, and the fruit interests of the lower Connecticut Valley, which have all been exceedingly profitable. (867, 870, 871, 875.)

Mr. Whitney says the truck industry has reclaimed vast areas of land in the Atlantic States. Twenty-five or thirty years ago the sandy soils along the coast were worth about \$1 to \$1.50 an acre. By the growth of vegetables they have increased in value until they sell now from \$50 to \$500 an acre in the natural state. (875.)

Mr. Whitney refers also to the important part which celery has taken in the reclamation of many areas of wet, mucky lands, and to the importance of the fruit industry in the reclamation of abandoned lands.

He particularly emphasizes the importance of vineyards as a means of reclaiming gravelly soils. The most valued soils along the Rhine are frequently so destitute of soil covering that the soil has to be maintained by stonework; yet on these very gravelly soils the finest varieties of grapes have been produced. Fruit trees and grapevines are declared to be a most important means of reclaiming otherwise worthless lands, particularly in stony areas. (877.)

Pineapples in Florida.—Mr. WHITNEY says there is a narrow strip of beach along the coast in southern Florida, extending from Jensen to Palm Beach, that was formerly comparatively worthless, but has been redeemed by the introduction of pineapples and is now worth from \$200 to \$1,000 an acre. Even the wild lands covered with the native jungle sell from \$100 to \$200 an acre when favorably located. Mr. Whitney instances this as a case of the reclamation of waste lands by specialization. The land is fertilized very heavily, the sand being used simply as a medium for the fertilizers. The soil would be of no value for general crops, but there is no other which can compare with it for pineapples. (875, 876.)

Mr. STOCKWELL, of Massachusetts, says the prosperous farmer is the one who has some specialty, some one thing in which he is trying to meet the present demand of the market, though not working on it exclusively. (895.)

8. Cooperative diversification proposed.—Mr. REDDING, director of the Georgia Experiment Station, does not think every farmer ought to grow everything he needs, but thinks diversified farming should be followed in a neighborhood by cooperation among the farmers. One man who has good wheat land should furnish wheat for all his neighbors; another with sugar-cane land should furnish sirup; another with rice land should furnish rice. Rice and wheat require milling, and it is not desirable for a man who wants 50 pounds of rice or 25 bushels of wheat to raise rice or wheat. The market should be arranged for before the crop is grown. (446.)

9. Need of public initiative.—Mr. POWERS says that the farming industry of the Eastern States has been revolutionized by the West, and that Eastern farmers who attempt to compete with the West will be ruined. They must find a new system of crops suited to the changed situation. It is the same, to a great extent, with the farmers of the South. The State ought to take the lead by ascertaining what new agricultural industries should be established. The Nation is not doing what it should in working out for the older sections of the country the methods and crops suited to those sections. (177.)

G. Products and resources of particular regions.—**1. Agricultural products of certain Northern States.**—*Vermont.*—Mr. SPEAR testifies that Vermont produces a surplus of nearly all agricultural products except grain. Wheat, corn, and oats are all brought from the West. Mr. Spear believes it is cheaper to raise corn in Vermont than to bring it from Iowa, and he thinks the farmers are coming to believe that it is better to raise more and buy less. The barley and oat crops have not been profitable. (408.)

North Dakota.—It seems to Mr. BUDGE that the climate of North Dakota is improving. Crops are grown there which could not be grown formerly. He attributes the change to the cultivation of the land. A little corn is now grown there, though it could not be grown when Mr. Budge went to North Dakota. (848.)

Mr. PROM says the chief products of North Dakota are wheat, flax, oats, and barley. (791.)

2. Products and possibilities of the South.—*Virginia.*—Mr. WEDDERBURN, master of the Virginia State Grange, says tobacco is the principal crop raised in the southern part of Virginia, while Loudoun and Fairfax counties send a great deal of milk to Washington and raise wheat and corn. Loudoun County raises some very fine cattle; there is a good deal of diversification. (621.)

West Virginia.—Mr. CLOHAN testifies that wheat and corn are the staple products of West Virginia. On the uplands the apple and peach are the two great fruit crops. Plums, cherries, and pears are also raised, and every fence corner has a cherry tree. (595.)

Kentucky.—Mr. NALL says the agriculture of Kentucky is greatly diversified. The crops include the grains, tobacco, hemp, blue grass, orchard grass, timothy, and, near the cities, potatoes. The southeastern part of the State, constituting districts Nos. 4 and 5 on the map accompanying Mr. Nall's testimony, is a mountainous section where the mineral and timber interests predominate, though there are some cultivated fields. Railroads are being run into this district and the mines and timber interests developed. Mr. Nall estimates that the farm products raised there are not sufficient to feed the people, now that there are so many miners. The money products are mostly logs, lumber, and minerals. Some common cattle are driven from this section and sold in the blue-grass region. Mining interests, principally coal, are considerable in the western part of the State also, and there is some very profitable development in petroleum in the mountainous region and along the Cumberland River. (806, 807.)

North Carolina.—Mr. WHITE testifies that cotton, corn, peanuts, and tobacco are staple crops in North Carolina. The principal crops are cotton and tobacco. In the spring early truck is grown to ship North, especially in the vicinity of Newbern. In the vicinity of Wilmington and the Cape Fear River rice, peanuts, etc., are grown. Some of the finest tobacco in the world is grown in the Lenoir district. (419, 420.)

Mr. White says the turpentine industry of North Carolina is nearly a thing of the past. (432.)

South Carolina.—Mr. HAMMOND, of South Carolina, says that there is a considerable amount of lumbering in the southern part of his State. A tract of lumber is bought very cheaply and the lumber cut off. Usually the turpentine is first taken out from the pine, and the Agricultural Department has shown that the lumber is better after it is taken out than before. The chestnut trees have been killed out by an insect. No care is given to the cultivation of forests in any part of the State. (833, 834.)

Mr. YOUNG testifies that there is considerable manufacturing in the upper part of South Carolina, but very little in the southern part. The depression of agriculture is so great and farm wages so low that the manufacturers can get their laborers much cheaper than they can in the North. (419.)

Georgia.—Mr. REDDING, director of the Georgia agricultural experiment station, enumerates cotton, corn, rice, sugar cane, peanuts, potatoes, and fruits as the principal agricultural products of Georgia. Cotton is the leading product, but near the coast rice is a crop of considerable importance. (443.)

Mr. Redding says Georgia is well adapted to the production of cereals; a large part of the State is well adapted to wheat and corn. Corn is now imported from States farther north, but chiefly for the city trade; as a rule the farmers now make a very good supply when crops are fairly good. They do not as a rule raise their own mules, but get them from Tennessee and Kentucky. (447.)

Mr. Redding says it is a common saying that everything but coffee can be grown in Georgia, and he believes it is true. Sugar cane can be grown successfully, and there is a tea farm started in Georgia. (450.)

Mr. STEVENS testifies that cotton is the principal crop grown in Georgia, and he places the value of this crop at \$54,000,000. Corn comes second, with a value of \$18,000,000. In the year 1900 there was a large peach crop, which put a great deal of money into circulation and employed a great many laborers during the dull season. He puts the value of this crop at \$3,750,000. The sugar-cane industry has made great progress, the manufacture of sirup in south Georgia having doubled in two years. The value of sugar and sirup amounted to nearly \$1,500,000. Mr. Stevens predicts that in the near future a number of sugar refineries will be established in south Georgia, which will give a great impetus to this industry. Tobacco of the best grades has been successfully raised in several sections of the State, but until recently only in a sufficient quantity to meet individual wants. The value of this crop is estimated at only \$27,000. Some of the most scientific farmers have undertaken wheat raising with excellent results, 40, 50 and even 65 bushels to the

acre having been produced. No country has a better supply of native grasses than Georgia, and the production of hay is increasing, as much as four tons of hay to the acre being raised. The main grasses are Bermuda grass, crab grass, and orchard grass, crab grass being the best. The new method of cutting, shocking, and shredding the cornstalk by machinery is very superior to the older method. The peavine makes very nutritious hay, as well as a splendid renewer of exhausted soils, and preserves those that are yet in good condition. Cotton-seed supplies in its meal and hulls rich food for stock, and contains a great deal of nitrogen which is useful in fertilizing the soil. The value of the rice crop is estimated at \$1,200,000, and that of the vegetable and apple crops at \$1,000,000 each. (914, 915, 917.)

Alabama.—Mr. POOLE, of Alabama, says that the Black Belt of Alabama is entirely an agricultural district, devoted to cotton and corn, very few other products being grown. The agriculture of the district is not very progressive, but conditions are improving. One may frequently find a graduate of Yale or Harvard living on his estate and directing, either in person or by a son or an overseer, the cultivation of his plantation. The State department of agriculture is encouraging diversified agriculture, and has distributed a large number of seeds of various kinds. The southeastern part of that State is inhabited by very thrifty small white farmers—the most intelligent farmers in the State—farming generally on the intensive plan and doing their own work. Among the eastern and sandy counties of Alabama the small farmers are generally prosperous and own their land to a very large extent. They have acquired lands since the war more rapidly than the colored men. (919, 921.)

Mr. Poole says Alabama is a wonderfully recuperative country. He has known farmers who have made a complete failure on their plantations, and been sold out by the commission merchant, to borrow \$1,000 and pay it back the first year. Mr. Poole regards Alabama as the most rapidly developing of all the Southern States. It has a healthful climate, plenty of water, and rich soil. If the negro laborers were a little more intelligent, all the improved farm implements could be used. The ignorance of the negroes, who are prejudiced against new ideas, is a great bar to success. (926, 927.)

Mississippi.—Mr. KYLE testifies that, besides cotton, sorghum, sweet potatoes, some sugar cane and Irish potatoes are raised in the hills of Mississippi, and meat is raised more than formerly. (467.)

Mr. Kyle says oats and corn can be raised successfully in Mississippi; the soil is not so well adapted to wheat. (473.)

Arkansas.—Mr. BALCH testifies that the northern half of Arkansas produces a considerable quantity of hay, wheat, oats, and various cereals. The southern half grows only enough corn, wheat, and oats for its own consumption. Sixty bushels of corn to the acre is nothing unusual in the neighborhood of Little Rock. (496.)

Louisiana.—Dr. STUBBS, director of the Louisiana Experiment Station, says Louisiana is unique in its agriculture. The southern part of the State is devoted almost exclusively to sub-tropical crops—oranges, sugar cane, and rice; farther north, cotton, corn, and stock are raised. Dr. Stubbs thinks the lower portion of Louisiana is perhaps more intelligently cultivated, and with more economy in methods, than any other portion of the world. The sugar and rice interests utilize every implement and process or method that can best economize production, and the methods of cultivation have improved vastly within 15 years. Everything that can economize labor is used. (770.)

Dr. WILEY declares that Louisiana is one of the best rice-producing States in the world, and predicts that it will in 50 years be the greatest rice-producing country. Rice is gaining and sugar cane is losing in Louisiana. (649.)

Opportunities in Southern agriculture.—Mr. REDDING, director of the Georgia Experiment Station, says the opportunities in Southern agriculture are considered very good by men who have come from the Northwest, accustomed to labor themselves. In Georgia a man worth \$4,000 or \$5,000 does not work on the farm, but hires somebody else to do it. The men from the Northwest come down to do their own work, and find the conditions very much more favorable than they would have found them 25 years ago. After they adapt themselves to the new conditions they are among the best farmers. Their plowing and hoeing is better, they use better tools, and are good patterns for Southern farmers to follow. Some of the Southern farmers have taken heart and become just as good farmers themselves. There has been considerable improvement in the last 20 years. (450.)

Mr. HALE, a fruit grower of Georgia and Connecticut, declares that the South has wonderful possibilities. He thinks that with intelligent business management there is a better opportunity for the investment of capital in agriculture in the South than elsewhere, on an average, because of the cheap labor and cheap land and the long season. He adds, however, that the white man with a very small capital is seriously

at a disadvantage in Southern agriculture. The number who earn something by working for others is very limited, because they must compete with 50 or 60 cent negro labor, working 12 or 14 hours a day. The Southern poor white has perhaps not as good a chance as the black man. (387, 394, 401.)

Mr. WHITE says North Carolina is rich in resources, and a good business man, white or colored, can accumulate a competence in agriculture. There is splendid farming land on the steepes of the mountains in the western part of the State. (422.)

Fruit.—Mr. HALE says a large section of Georgia and northern Alabama and sections of South Carolina and Tennessee are adapted to fruit growing. Georgia is a wonderful State for grape growing. The grapes drop from the bunch, but are of high quality and rich in sugar; there is a fine opportunity to grow them for wine making. Mr. Hale doubts if Georgia can compete with California in growing prunes, and the European plums grown elsewhere in the United States will not thrive in the South; but Japanese plums are grown with wonderful success, and are preferable to anything that can be produced in California. Because of their tough skins they can be shipped all over the United States, and worms are rarely found in them. Mr. Hale has found Japanese plums with marks of the curculio on the skin, but not a single worm in any of them, though he has looked for them for a number of years. A Cornell University scientist says the skin is so thick and tough and grows so rapidly that it crushes the egg before it is hatched. This plum is not troubled with black knot, and can be grown as cheaply as apples. It can be grown all over the United States, but is particularly suited to the South. Blackberries grow wonderfully in Georgia. Mr. Hale suggests the production of canned fruits and evaporated fruits, declaring that Georgia can make a higher quality of canned fruit than California. (382, 394-396.)

Nurseries.—Another industry suitable for the South, in Mr. Hale's opinion, is the growing of nursery stock, which is expensive to produce in the North on account of the high price of labor. Georgia, he says, can grow as fine a fruit tree in 1 year as the North can produce in 2 years. The Baldwin apple, the Concord grape, and the Bartlett pear will thrive equally well in any part of the country, whether propagated in the North or in the South. Mr. Hale gives an interesting account of the way in which fruit trees adapt themselves to a new climate. A number of nurseries were started in Georgia on a large scale, but could not compete with the North on account of the excessive freight rates, which were apparently made for local business. Georgia nurserymen started in a small way to grow plum stocks, which have always been imported from France, but there was hardly a profit in it until the McKinley tariff act put a duty on the stocks. The duty was taken off by the Wilson bill. (395, 396.)

Nuts.—Mr. HALE says we import many hundreds of thousands of dollars' worth of nuts from European countries. The pecan can be grown to advantage in many sections of Georgia, and is grown to some extent. Mr. Hale has grafted the Japanese chestnut on the American chestnut, and produced nuts as large as horse chestnuts and as sweet as the native American chestnut, for which he was paid 40 cents a pound at wholesale in New York. A train load could be sold at 10 cents a pound or \$5 a bushel. He estimates that about 60 or 75 bushels can be grown to the acre. These nuts have never been troubled by the weevil, as the American chestnuts are. (394.)

3. *The Pacific coast.*—Mr. NAFTZGER says the climatic conditions of the Pacific coast are such that almost everything is produced there except purely tropical products. California produces cereals largely and fruits in great variety. The Pacific coast is not a manufacturing country, but depends rather upon its minerals, its agricultural and horticultural products, and lumbering, manufacturing being retarded by the high freight rates. It is only within the last 3 or 4 years that the exports from California have exceeded the imports, but for the last year or two they have exceeded the imports by nearly 50 per cent. Mr. Naftzger thinks this applies also to Washington and Oregon. (949, 950.)

Mr. TURNBULL states that, though California can hardly yet be classed as a manufacturing State, the list of manufactures is considerable and the value is large. He anticipates a great growth of manufactures to accompany the increasing trade with the Orient. (981.)

Petroleum.—Mr. TURNBULL says that there are now about 200,000 producing oil wells in California, owned by more than 250 companies. Prospecting is going on throughout the State. The value of the oil lands, including the plants, boring outfits, tankage systems, pipe lines, etc., amounts to \$200,000,000. The cost of drilling an oil well to the depth of 1,000 feet, exclusive of the cost of casing, is said to be from \$1,000 to \$3,500 in Los Angeles and in the Kern River district, and to go up as high as \$5,000 and even \$7,500 in other regions. Mr. Turnbull presents a table giving the yield of crude

CXXLVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

petroleum in California by years. One hundred and seventy-five thousand barrels is said to have been produced before 1876, and in that year 12,000 barrels. The yield rose gradually to 385,000 barrels in 1892. From that time the increase has been more rapid. The yield for 1899 is given as nearly 2,700,000 barrels, and that for 1900 is estimated at 4,000,000 barrels.

Some illuminating oil is produced in California, but probably nine-tenths of the petroleum is suitable only for fuel. It is used for that purpose in Mr. Spreckels's great sugar factory, and in the cotton mills at Oakland. The Santa Fe and the Southern Pacific use it in their engines. The Union Iron Works at San Francisco are preparing to use it. Oil at \$1 a barrel is said to be equivalent to coal at \$4.50 a ton. The cost of coal in California is about \$7.50 a ton. (986, 987.)

Commercial advantages of San Francisco.—Mr. TURNBULL declares that San Francisco has the largest and most accessible harbor on the Pacific coast. It lies within 90 miles of the shortest sailing route from the Isthmus to Yokohama, and within 200 miles of the shortest sailing route from the Isthmus to Hongkong and the Philippines. It will, therefore, be a way station for all vessels going between the Isthmian canal and Asiatic ports. The greater part of the overland traffic to the Orient must also be tributary to San Francisco; all except that northern fraction which originates in the latitude of Puget Sound. While there will be large and important cities in Washington and Oregon, San Francisco must occupy a position on the Pacific coast comparable with that of New York on the Atlantic. The equable temperature is a unique economic advantage. (982, 983.)

Cost of living in California.—A statement by the president of the State board of trade of California, presented by Mr. TURNBULL, asserts that the prices of the necessities of life—fruit, vegetables, meat, flour, etc.—are lower in California than in the East. California has a large surplus of all these things, except meat, to ship to the East. The price of wheat is the price in Liverpool, less transportation. The cost of clothing for the laborer is also less than in cold countries, because less protection for the body is required. (988.)

Mr. Turnbull says that the cost of groceries in California now averages about the same as in 1896. Hardware and house-furnishing goods are about 15 per cent higher. Meats are about 10 per cent higher. Drugs and medicines are from 5 to 10 per cent higher. Clothing is about 10 per cent higher. Dry goods are from 5 to 10 per cent higher. Coal is the same as in 1896, but wood for fuel has gone up 15 or 20 per cent. The rents of such houses as are usually occupied by workmen are the same, or from 5 to 10 per cent lower. Newer and better classes of houses are a little higher. (977.)

Wages.—Mr. Turnbull discusses the causes of the high wages in the early days of California, and the causes of the decline. So long as there is untilled land at the disposal of the State, he says, or for sale at a reasonably low price, the wages of hired labor must equal the returns of labor applied to the land. So, too, as long as there were many unclaimed placer mines easily available, the wages of other industries had to be high enough to compete with the advantages found there. Various explanations of the decline of wages have been offered. One is that the land has been withdrawn from the market, or is held at such prices that no greater advantage can be got from the purchase of it than from the purchase of land in older communities. Another suggestion, which presupposes this, is that many would-be settlers of small means have come to California under the impression that cheap lands could still be got, and, finding themselves disappointed, have crowded into the cities to compete for such work as they can do. Another and still more popular theory finds the explanation in the competition of the Chinese and Japanese. This, Mr. Turnbull thinks, has only aggravated and intensified the effect of forces already at work. The primary reason of the low wages of unskilled Chinese laborers is their incompetency, though Mr. Turnbull afterwards admits that their ability to live much more cheaply than American workmen is, perhaps, even a greater factor in the result. But Chinamen learn very readily when they have opportunity, and when they have acquired skill, as for instance, the Chinese cooks do, they command such prices that they can no longer be said to depress wages.

Mr. Turnbull thinks it a mistake to attribute the fall of wages to any single cause. The conditions of the separate classes of workers should be considered separately.

The first class consists of skilled laborers producing goods for a greater market than the State of California. This class consists chiefly of the skilled labor engaged in the production and preparation of fruit and wine. In such industries the excess of wages over wages in competing places can not exceed the difference of natural advantages, diminished by the greater cost of transportation from California. As the natural advantages are more and more appropriated they lose their influence on

wages, and the workers who employ them tend to get only what similar workers get elsewhere.

The second group consists of the industries which produce goods competing in the local market with goods that can be imported from outside the State. The principal advantage here is the cost of transportation. If there is a little gain in ability to gauge the market and a little gain in the ability to use raw material produced within the State, these advantages are offset by the higher rate of interest in California. Such industries do not arise until comparatively late, and as soon as they do arise wages in them will conform closely to Eastern rates.

These industries stand at one end of the scale. At the other end are all those trades which require skilled labor and in which the whole of the work must be done on the spot. It is here that the local advantages are longest maintained. The first report of the California Bureau of Labor Statistics contained a comparison of wages in certain trades between California and New York and Chicago. The report referred to the year 1883-84. The California wages seemed to be higher by an astonishing amount. If the report is carefully examined, however, it is seen, says Mr. Turnbull, that almost all the trades mentioned fall within this third group. They are certain building trades, together with blacksmiths, bakers, shoemakers, cabinetmakers, coopers, printers, tinsmiths, and brass founders. These trades were probably not selected with an intent to deceive. They were naturally chosen because they had arisen early in the community and had attained importance in it. But the selection of them was deceptive, because they are exactly those trades which are not subject to competition by the transportation of their products. Wages in these trades are still higher in California than elsewhere, but there has been a decided fall since the report referred to. This can be explained by the movement of labor toward such trades and the inevitable equalizing of wages. The fact that this class of workmen still maintains an advantage, however, seems to Mr. Turnbull to be an argument against the validity of the first-suggested cause of the fall of wages—the increase of land values.

The fourth group is composed of unskilled laborers. This class gains most in newly settled communities, says Mr. Turnbull, from the cheapness of land, and, on the other hand, is the first to feel the movement toward different conditions.

Mr. Turnbull presents a table taken from the report of the Interstate Commerce Commission for the year ending June 30, 1894, showing the compensation of various classes of railway employees in the United States as a whole, in Group 10 (west of the Rocky Mountains), and in certain Eastern and Central States. A considerable difference in favor of Group 10 is shown. Mr. Turnbull asserts that the highly skilled men have the largest proportional advantage, but he does not undertake to support the assertion by an analysis of the figures. Mr. Turnbull remarks that railroad employees belong to the class of workmen which is able to retain longest the benefit of the economic advantages of a new country; namely, the workers at those employments which require skilled labor and in which the work must be done on the spot. (971.)

Mr. Turnbull sums up his conclusions as follows:

"For the unskilled labor the rate of wages in California already conforms to the rate paid elsewhere: First, because the natural advantages which could be used by such labor are mostly monopolized; second, because a large part of the unskilled labor is peculiarly inefficient. A few lines of skilled labor employed in industries exploiting peculiar natural advantages still earn large wages. Many lines of skilled labor, of such a sort that the work is done on the spot, obtain slightly higher wages than prevail in the East, and will do so as long as the advantages enjoyed by the first class of skilled labor are not all appropriated. The rate of wages enjoyed by skilled labor producing commodities which compete in the California market with commodities manufactured outside are higher by part of the cost of transportation, and this will be the first class of skilled labor to lose the advantage which it enjoys."

Mr. Turnbull submits a table purporting to give both nominal daily wages and average yearly earnings in a considerable number of employments. (969-972, 976.)

Mr. Turnbull adds that from 1894 to 1896 a great part of the workmen of California were without employment. Of those that were employed, such as escaped direct reduction of wages had to work less than full time. When the tide turned the first result was full time and the absorption of the idle labor. Then increase of pay began and grew more frequent, until now demands for more pay and fewer hours of work are heard in all directions, and are granted. (977.)

Savings bank deposits.—Mr. TURNBULL states that in 1892 over \$95,000,000 was deposited in the savings banks of California and over \$83,000,000 withdrawn, leaving a net gain of over \$12,000,000. In 1894 nearly \$97,500,000 was deposited and over \$104,000,000 withdrawn, showing a large diminution of deposits. In 1899 the deposits were \$77,500,000 and the withdrawals less than \$72,000,000. Mr. Turnbull assumes without question that the savings banks "are the workers' depository, and by the rise

and fall of deposits therein the workers' comparative prosperity can be measured as by a barometer." (975, 976.)

Labor organizations.—Mr. TURNBULL states that the hat finishers' union of San Francisco is said to date from 1853, and that there are 6 unions in the city that were formed during the Kearney movement. Most of those before 1880, however, were rather social and political clubs than strictly trade organizations. It was not until the special advantages of the situation of workmen in California began to disappear that the movement made great headway. The greatest increase of trade unions in numbers and strength took place from 1884 to 1890. The results have been permanent, but the increase has not since then been so rapid. In 1888 the Bureau of Labor Statistics estimated that there were about 20,000 members of labor organizations in the State. A conservative estimate now places the membership at from 40,000 to 45,000. There are few important industries, if any, which are not organized, and there are many organizations of the unskilled. Even the Chinese have their unions, called "tongs," though on account of their extreme secrecy no trustworthy information about them can be given.

The initiation fees vary from 50 cents to \$10; the monthly dues from 10 cents to \$5, but mostly less than \$2. A large proportion of the unions pay sick and death benefits. Sick benefit seems to be usually about half the regular union wages. The death benefit provides a decent burial, and in some cases a little more. It varies from \$50 to \$250. Strike pay is generally smaller than sick benefit. A few unions have an out-of-work benefit.

The most of the local unions belong to larger associations of their trades, extending throughout the United States and Canada. The local unions in each important city or county are for the most part united in local federations. These associations vary in form, from that of a loose federation to that of a strong body, to which all important questions are referred. The office of the federation is generally open all the time, and serves as a means of communication between the different unions, and sometimes as an intelligence office to men out of work. The rules of most of the federations do not allow the individual unions to strike without the consent of the council of the federation. A local union that desires to strike has first to convince the other unions, therefore, of the justice of its intention. In most cases it must also submit the matter to the central authority of its national trade union. In many instances the necessity of thus showing the reasons for the strike, together with the conciliatory attitude of the federation officers, has prevented serious trouble.

The local federations have recently united in the Pacific Coast Council of Trades and Labor Assemblies. This association is yet very weak. It is supposed to meet once a year, and to be composed of delegates from all the unions on the coast. But the expense of sending delegates to the meetings of the national trade unions, usually held in the East, is so great that the unions hesitate to incur the additional expense of sending men to this convention also. The aim of the council is to care for those interests of the unions that are peculiar to the whole of the Pacific coast, such as the regulation of the hours of labor by law, and the like. (973, 974.)

Mr. Turnbull says that the establishment of unions has brought the California workmen into touch with the labor movement elsewhere, both by actual affiliation in organization and, even where that does not exist, by the closest affiliation in thought. This adds materially to the forces that tend to break down the economic isolation of the State. Too close an affiliation with Eastern unions is likely to be at the cost of the California union. In those industries in which the Western workmen have an advantage they are likely to be the heaviest contributors to any cause calling for financial support. If the unions are strong enough they may retain some of the peculiar advantages of a new community longer than would otherwise be possible, but in the main they have little power to retard the gradual change of conditions. (974, 975.)

Mr. Turnbull says that labor organizations in California, as elsewhere, have been the favorite field in which the advocates for cures for social and economic evils have worked. The Socialist Labor Party carries on a continual but moderate agitation, and sometimes influences the unions in their policy. From time to time the unions have seemed to indorse one or another social specific. Sometimes a newspaper, run in the interest of some hobby or of some political party, has appeared as the organ of the unions, with or without their direct sanction. Such papers seldom represent the thinking members of the unions. These members are, for the most part, sober-thinking, conservative men, and many of them are property owners. The constitutions of many unions forbid the discussion of political or religious questions at their meetings, and these provisions are understood to be generally enforced. Whatever views the members may hold, the unions, as such, do not often enter politics. The

leaders have sometimes abused their powers and been more arbitrary than any employer, but these tendencies are apparently passing away. (974, 975.)

California State Board of Arbitration.—Mr. TURNBULL says the State Board of Arbitration of California is almost useless, because it can not move until it is called upon by the parties to the dispute, and that rarely happens. (974.)

X.—THE SUGAR INDUSTRIES.

A. Development of the beet-sugar industry.—1. In Europe.—Dr. WILEY, Chief Chemist of the United States Department of Agriculture, testifies that the beet-sugar industry was established as an industrial occupation in Europe by the first Emperor Napoleon. On account of the embargo which England laid on European ports, the colonial sugar was practically excluded from France and the whole Continent of Europe, and to remedy this the Emperor made a grant of money in the form of a subsidy to encourage the establishment of beet factories in the Empire. This was about 1809 and 1810. The fall of the Emperor interrupted the State bounty, but the industry had taken such a hold in France that it continued to grow, and by 1830 France made a very considerable quantity of beet sugar, as measured by the markets of that period. The Germans, who had been the first to discover the merits of the beet as a sugar-producing plant, were not slow to follow the French, and before the end of the sixties German production had overtaken that of France. It is now double that of France. (638.)

Germany.—Dr. WILEY submits a statistical statement showing in a striking manner the progress of the beet-sugar industry in Germany from 1840–41 to 1898–99. The yield of sugar shows an increase from 5.88 per cent to 13.37 per cent, the development of processes for recovering sugar formerly lost in the molasses having contributed considerably to this increased yield. During this period of 60 years the sugar production has increased from 15,659 to 1,793,538 tons of 2,000 pounds, while the importations of sugar have decreased to 1,236 tons. The Empire's export trade in sugar has increased until more than one-half the entire product is sent abroad. "The application of scientific methods in the field and in the factory has greatly assisted in attaining this result, but it has only been possible with the aid of most favorable revenue and tariff laws."

Dr. Wiley testifies that the great production in Germany has been secured by bounties, but they have never been paid to the grower or to the manufacturer unless an exporter. The bounty is paid to the man who exports the sugar. The man who grows the sugar has to pay a heavy tax. The German Government collects more in the tax on its beets than it has ever paid in bounty. The average tax on every ton of beets grown in Germany was until recently nearly \$4. A corresponding tax is now levied on sugar consumed within the Empire. Every factory is run like a distillery; a Government officer stands at the scale and keeps the data of all sugar exported.

"A very high tax on imported sugar has been maintained since 1840, with a differential in favor of the German refiners until 1887. An export bounty, also with a differential in favor of German refiners, has stimulated production for export. From 1841 to 1892 an internal-revenue tax was levied on beets used for sugar production. Since 1889 this has been replaced by a corresponding tax on sugar consumed within the Empire. The export bounty was reduced at the same time the manufacturers were relieved of the tax on their raw material."

"Among the important effects of this system of sugar laws there must be mentioned besides the stimulation of production, the depression of domestic consumption of sugar, and the embarrassment of the refiners of sugar in England and of the raw-sugar producers in colonies of that country. Moreover, the system has yielded the Government a net revenue varying from 0.31 to 1.99 marks per capita per year."

Dr. Wiley submits a tabular statement of Germany's sugar laws, inland and import axes and export bounties on sugar, with the gross and net revenues from these sources, the quantities of sugar exported and imported, and the annual consumption per capita in Germany from 1840 to 1899. (655, 656, 658–661.)

2. In America.—Dr. WILEY testifies that the first attempt to introduce the sugar-beet industry in this country was made in 1835 by an association of agricultural and scientific men of Philadelphia, who employed an agent to visit France. As the result of his report an attempt was made at Northampton a year or two afterwards to grow beets for sugar, and several tons of sugar were made. The first chemist of the Department of Agriculture made analyses of sugar beets as early as 1862, just after his appointment; but the Department's first systematic work toward promoting the industry in this country was accomplished during the Paris Exposition of 1878. Dr. McMurtrie, who was at that time chemist of the Department, was detailed to go to Paris in charge of the exhibit from this country, and was charged with studying the beet-sugar industry with a view to its introduction into the United States. He made

a very elaborate and valuable report, and supplemented it with investigations the next year in this country. As an indirect result of this investigation capital was largely interested in the industry in 1879, 1880, 1881, and 1882, and quite a large sum was invested, especially in the New England States and in Delaware. In Delaware a large factory was built, another was built at Franklin, Mass., and a third in Port land, Me. These factories were all equipped with the most improved machinery then known, and should have been a success in manufacture, but they all resulted in disaster, solely on the agricultural side. (638, 639.)

In 1884, Dr. Wiley was instructed by the Commissioner of Agriculture to study the remnants of the sugar-beet industry in this country, to see if it could be revived. He visited the factories which had been established in the East, and also went to California, which had the only factory which remained in operation from the impetus given in 1878 and 1879. This was a small factory with a capacity of only 80 tons of beets per day at Alvarado, near San Francisco. This was one case where growing had gone ahead of manufacture. Beet growing had proved so profitable that the farmers had overwhelmed the factory with beets, and over 20,000 tons of beets were lying in one pile, almost hiding the factory. (See Bulletin No. 5, Division of Chemistry, pp. 73 et seq.) During the next few years investigations were made on beet sugar, among other subjects, and in 1890 a series of special experiments in the production of high-grade seeds was begun at Schuyler, Nebr. (640, 641.)

Dr. Wiley says that while the best beets would naturally be supplied along the northern borders of this country, because the farther north a crop can be produced in time to harvest and deliver it before the advent of winter the better the chances of success, the Department of Agriculture has exploited every part of the country. Seeds have been sent to experiment stations in every State, with a uniform system of directions for planting and cultivation, and also to farmers (6,000 a year on an average) who would promise to conduct the work according to instructions. Analyses have been made at the experiment stations and also at the laboratories of the Department of Agriculture. This work has been continued more than 10 years. (644.)

Mr. Ssow testifies that the American beet-sugar industry is developing very rapidly, and that the manufacture of beet sugar is becoming a very large industry in the central west. In the 2 years 1897 to 1899 there was an enormous increase in the production of beet sugar. (241.)

Mr. Saylor testifies that 30 beet-sugar factories were in operation in this country in 1899. Of these California had 8 (including the largest in the world, with a capacity of 3,000 tons of beets or 300 tons of sugar daily), Michigan had 9, Nebraska 3, Utah 2 factories and 1 subfactory, New York 2, and Colorado, Minnesota, Illinois, Washington, Oregon, and New Mexico 1 each. Six or more were projected or building early in 1900, including 2 in Colorado and 1 each in New York, Ohio, and Michigan. (585, 586.)

New York.—Mr. Rogers, president of the Binghamton Beet Sugar Company, testifies that the first beet-sugar factory in New York State was built at Rome in 1897. The Binghamton Beet Sugar Company was organized in the spring of 1898, after experiments had shown that beets sufficiently rich in sugar could be grown in New York, and manufactured sugar from about 10,000 tons of beets that year and from about 13,000 tons of beets in 1899. New York has the climate and soil for growing beets, and they can be manufactured there as cheaply as anywhere. The important factors in manufacturing beet sugar, besides the beets themselves, are chiefly coal and limestone, both of which can be obtained near at hand. The success or failure of the beet-sugar industry rests with the farmers, who must have a good deal of education to grow the beets successfully. They require much more thorough cultivation and much more work than the average farmer puts on the average crop. The farmers who take the best care of their crops are making the best success with them.

Sugar beets require soil that is well drained and comparatively free from stone, and deep and thorough cultivation. The Binghamton Beet Sugar Company asks the farmers to sow not less than 14 pounds of seed to the acre, in order that every row may be full. The company employs men and keeps them in the field all summer to give help and instruction to the farmers. The average yield of the crops harvested in 1898 was 6 tons to an acre, and in 1899 8 tons to an acre, although the season was the driest for 20 years. Mr. Rogers does not think a yield of more than 10 or 12 tons to the acre can be counted upon, at least until the farmers are more thoroughly versed in the cultivation of the beets. The cost of preparing the ground, sowing, thinning, cultivation, and harvesting need not exceed \$30 an acre; many farmers have paid as much as \$40 and \$45 an acre for this labor, others less than \$20. The State of New York pays a bounty of 1 cent a pound on all sugar made from beets grown in the State, on condition that the farmer received \$5 a ton for the beets.

The Binghamton Beet Sugar Company has never refused any beets offered by farmers with whom it had a contract, although a few lots of beets gave less than 12 per cent of sugar; it pays a uniform price of \$5 a ton. The average percentage of sugar in 1899 was between 12 and 13. Mr. Rogers says the farmers who have taken care of their crops have, as a rule, made a profit of more than \$10 an acre, and a profit of \$20 an acre is within the range of reasonable expectations. Smith & Rowell, of Syracuse, who have been in the nursery business and understand gardening, grew more than 12 tons an acre, receiving about \$8,000 for 130 acres. In exceptional cases men have grown 25 tons to the acre. Mr. Rogers thinks there is no more profitable crop for the American farmer than the sugar beet, properly cultivated. Where there have been failures they have been due chiefly to the lack of a full stand and to neglect in cultivation. The company advises the farmers to sow in rows 18 inches apart, and then to thin, leaving a beet for every 8 inches in the row. (549-552.)

Mr. Rogers says a soil and climate producing fruit in perfection, like that of New York, is exactly what is wanted for the sugar beet. (552.)

Mr. Rogers thinks land suitable for growing sugar beets in the vicinity of Binghamton would be worth \$100 an acre, and rent for \$10 an acre. (560.)

Michigan.—Professor KEDZIE, of the Michigan Agricultural College and Experiment Station, testifies that in 1881 the legislature of Michigan passed "an act to encourage the manufacture of sugar," exempting the apparatus used from taxation for 5 years and offering a bounty of \$2 for every 100 pounds of sugar. Under this law 10 tons of sugar were made from sorghum and \$404 paid as bounty. It was found that sorghum as grown in Michigan was not profitable for making sugar, because the proportion of glucose was too large. The glucose is very difficult of crystallization and only two-fifths the sweetness of sucrose, and renders an equivalent amount of sucrose uncrystallizable. Attention was then turned to sugar beets. In 1890 the college imported 200 kilograms of each of 4 kinds of sugar-beet seeds from Europe and sent them to farmers in all parts of the Lower Peninsula, with directions for planting, cultivating, and harvesting the beets. Of 400 farmers receiving seed, 228 reported results and sent beets for analysis. These reports came from 39 counties. The average content of sugar in the juice was 14.2 per cent, and the coefficient of purity (the proportion of readily crystallizable cane sugar present in the juice as compared with the total amount of solids there present) was above 80° in 200 of the specimens. The estimated yield of beets per acre was 13 tons. The adaptability of Michigan to produce sugar beets of high quality was thus demonstrated, but capitalists and manufacturers were not ready to enter upon the business. In 1897 general interest was awakened in the subject and legislation was secured to promote the manufacture of beet sugar. The legislature passed an act (introduced in full in the testimony, pp. 541, 542) offering a bounty of 1 cent a pound for all sugar (at least 90 per cent crystallized) manufactured in the State from beets grown in the State, provided at least \$4 per ton of 2,000 pounds were paid for all beets containing 12 per cent of sugar. Aid from the Department of Agriculture in furnishing seeds and transportation by mail greatly assisted the efforts of the college. The seed was sent to many leading farmers who would undertake to raise at least 1 acre of beets, and also to a large number of amateurs. Although the season was only a fair one, the beet crop was quite satisfactory. The specimens of beets received for analysis numbered 493, from 64 counties. The average content of sugar in the juice was 16.08 per cent and the coefficient of purity in most cases was 80° or above, some going as high as 92°. In most of the cases of low purity the beets were grown on mucky soil. (535, 536, 540-542.)

The results of the years 1897 and 1898 were so satisfactory that farmers looked for equally good results in 1899, but the weather was so unfavorable (the most severe drought since 1864 occurring during the growing season) that the crop was very unsatisfactory in many localities; and though other crops had suffered even more severely, the farmers in some of their meetings passed resolutions not to plant sugar beets. (537, 538.)

Professor Kedzie testifies that under the stimulus of the bounty 9 factories have been erected in Michigan, and others are projected. The addition of another cash crop was welcomed by intelligent farmers, and the price of farm lands in the vicinity of the factories increased \$10 an acre. Only 1 factory had received the benefit of the bounty at the date of Mr. Kedzie's testimony (May 1900). The Michigan Sugar Company, of Bay City, received \$28,451 in 1898. The legislature passed a bill in 1899 reducing the bounty to one-half cent a pound and appropriating \$200,000 to pay the bounty. The governor vetoed this bill, leaving the State without funds to pay the bounty, but leaving the bounty law in full force. Claims for bounty amounting to \$300,000 for 1899 were pending at the date of the testimony. (542.)

Mr. SMITH, director of the Michigan Experiment Station, says the experiments made in 1890 and 1891 with sugar-beet seed imported by the experiment station from Germany showed that sugar beets of good quality could be grown in all parts of Michigan south of a line drawn east and west through the southern boundaries of Manistee and Iosco counties. Frequent failures in the wheat, fruit, and clover crops during the next few years created an active demand among the farmers for a new crop. The farmers of Michigan are for the most part native-born Americans, accustomed to the growing of cereals and not to intensive agriculture, but repeated failures of the usual crops made them ready to welcome any new crop that gave promise of adequate financial returns. (563, 567.)

Referring to the diminished yield in 1899, Mr. Smith says: "It was assumed that the almost phenomenal results obtained on a peculiarly favorable soil in a peculiarly favorable season by experienced beet raisers would be duplicated on less favorable soils by inexperienced farmers regardless of the season." The farmers all over the State were aroused from apathy to unbounded confidence in the new industry. (568.)

Mr. Smith adds that notwithstanding the adverse season in 1899 some farmers harvested 18 to 20 tons to the acre and made a fair profit. The profit compared very favorably with that from the wheat crop, which was nearly a total failure. Some farmers abandoned the fields after thinning, but in sandy localities many acres were plowed up without any loss except for the seed, and the fields utilized for other crops. (577, 580.)

The season of 1899 was so unfavorable, and the attitude of the average Michigan farmer toward the sugar factory is such, that the Kalamazoo and Rochester factories found it almost impossible to secure beets in 1900 from the territory that supplied them in 1899. The Kalamazoo company contracted for 5,400 acres, of which 2,200 acres were in Indiana and 1,000 in Ohio. The Wolverine Sugar Company, at Benton Harbor, is in the best fruit-growing section of the State, and also has to compete with large canning and pickling factories at Benton Harbor and St. Joseph. As a result, it secured its acreage for 1900 very largely from Indiana. (572.)

The acreage devoted to the culture of beets in Michigan in 1899 was about 35,000 acres. Mr. Smith thinks more than 37,000 were contracted for by May, 1900; all the factories had a sufficient acreage except those at West Bay City and Detroit. (580.)

North Dakota.—Mr. BRIDGE says sugar beets are raised even in the eastern part of North Dakota, but they are not so productive of sugar as those raised farther west. There is a difference of 4 or 5 per cent in favor of the dry north lands; in the eastern part of the State the beet grows larger, and there is more starch in it. In the western part of the State sugar beets are considered a profitable crop. (853.)

Virginia.—Mr. WEDDERBURN says some sugar beets have been grown near Winchester, Va., and he understands that the analysis of the beets sent to the Department of Agriculture was satisfactory. Mr. Wedderburn himself has raised some nice beets, but he knows of no sugar-beet industry in Virginia at present. He quotes Dr. Wiley as expressing the opinion that, except for the vicinity of Winchester, Virginia is rather out of the sugar-beet line. (625.)

Louisiana.—Dr. STEBBES says sugar beets have been tried everywhere south of the Ohio River, but can not be grown successfully in the South, the sugar content being insufficient. They can not be grown to advantage in Louisiana in the summer time because the heavy rains which make the sugar cane and rice profitable are very destructive to the sugar content of the beets, which weigh from 10 to 13 pounds in October and have less than 2 per cent of sugar. A number of experiments have recently been made with winter sugar beets, 1 year with very great success. They were planted in September and October and harvested in January, and beets were grown containing as high as 18 per cent of sugar, but the next year the frost of 1899 destroyed the crop. (774.)

Canada.—Dr. WILEY says an excellent quality of beet is grown in Canada, but on account of the early winter the time for harvesting is so limited that the industry has not proved so profitable as farther south, where the beets are not quite so good. (645.)

California.—Mr. TURNBULL states that an average crop of beets on good land in California is 12 to 15 tons per acre. Many growers obtain much more. The average cost of raising an acre of beets and delivering them on board cars or at the factory, including the seed and wages for all the work, is \$20 to \$25. Mr. Turnbull presents a table showing the production of beet sugar in the State from 1888 to 1899 in tons of 2,000 pounds. The crop in 1888 was 1,910 tons. It rose gradually to 35,280 tons in 1897. The production of 1898 is given as 18,086 tons and that of 1899 as 32,445. A note explains that the output for 1899 would have exceeded that of any previous

year if it had not been cut down by the drought where there was no irrigation, and that the yield hereafter will show a marked increase. (979.)

Mr. Turnbull states that the sugar beets grown in California run from 12 to 14 per cent sugar. There are now 8 plants in the State, representing an investment of over \$10,000,000. Ten years ago there were 2 factories. The machinery is partly imported and partly made in the United States. Mr. Turnbull does not know of any combination between the factories. (980, 981.)

Mr. Turnbull summarizes the advantages of California for beet raising as follows: Earlier maturity of the beet; earlier opening of the campaign; long season for harvesting; long run of the factory; greater yield per acre; greater per cent of saccharine; immunity from frost, and immunity from rain at critical periods. (979.)

Mr. NAFTZGER enumerates the following beet-sugar factories in California: The Chino and Oxnard establishments, both owned by the Oxnard Company; the Alamos, owned by Senator W. A. Clark; the Watsonville, Spreckels, Alvarado, and perhaps the Crockett are, he thinks, all owned by Mr. Spreckels. Mr. Naftzger is inclined to think that there is a sugar combination in California. The product of refined beet sugar in 1899 was 42,000 pounds; in 1900, 30,000 pounds; the crop was nearly a failure that year in southern California, where there are 2 large factories, because of drought. Mr. Naftzger thinks that the farmers engaged in beet raising have had uniformly profitable results except in that dry season. (950, 951.)

3. Ownership of factories.—Mr. SAYLOR testified in May, 1900, that the American Beet Sugar Company had 2 factories in California, at Chino and Oxnard, and 2 in Nebraska, at Grand Island and Norfolk, and was building a fifth. The remaining factories were entirely separate and independent. (590.)

Mr. SMITH has not heard of any beet-sugar trust. The Michigan factories work entirely independently and no organic combinations have been proposed. (582.)

4. Bounties.—*New York.*—Mr. ROGERS testifies that the New York bounty is 1 cent a pound on sugar from beets grown in the State that polarize 90 per cent or above. All the sugar made in his factory comes above the standard. The State appoints a weighman to weigh sugar and select samples to send to the State Chemist for analysis; his salary of \$5 a day is paid by the factory. (558.)

Mr. ROGERS goes on to say that the New York sugar-bounty act provided that the bounty should be paid for at least 5 years. The first year the appropriation was \$25,000; in 1900 it was \$50,000, and there was \$30,000 in the fund. The intention of the bounty was to aid the farmers. Factories would not pay \$5 a ton for all beets if they did not receive a bounty. Of the bounty fund \$7,500 is appropriated to pay 5 men, selected by civil-service examination, to go among the farmers and instruct them in the raising of beets. They visit each farmer who grows sugar beets 2 or 3 times during the season. It is an incentive to the farmer to take good care of his crop if he knows that some one is coming to look at it and compare it with those of his neighbors. It is not sufficient to publish pamphlets; the average farmer neither reads all that is published for him, nor follows all he reads; it needs someone to go into the field and show the farmers how to plant and cultivate the crop. (560, 561.)

Michigan.—Mr. SMITH testifies that the Michigan sugar bounty is 1 cent a pound for all sugar grown from beets grown in the State, for which the factory pays \$4 a ton for beets containing 12 per cent of sugar, with an addition for each additional per cent of sugar. (569.)

Bounties criticised.—Mr. SAYLOR says the bounties are never carried out; the contracts implied in the laws are annulled as soon as the factories are started and the money begins to be drawn from the treasury. In Michigan 8 or 9 factories have brought suit for their bounty. Nebraska has had the same experience; after two factories were started the next legislature refused to make the appropriation for the bounty, and the matter went into the courts.

Mr. Saylor also criticises State bounties as producing inequality among the States, and as unnecessary. He approves the offering of a small bounty for 2 or 3 years (since it takes a factory a year or two to adjust itself to conditions), but says any bounty offered ought to be national. (589, 590.)

Permanent bounties unnecessary.—Mr. ROGERS thinks the bounty has been necessary to encourage the beet-sugar industry in New York. The 500-ton plant at Lyons would not have been built except for the bounty, and he does not think his own factory would have been. He does not think the industry should be fostered continuously, however. (560.)

Professor KENZIE does not think a permanent bounty necessary. He thinks that a bounty of from one-fourth to one-half a cent a pound for 2 to 4 years would be sufficient to establish the factories, and that from that time on they would be self-sustaining. (543.)

Exemption from taxation in Iowa.—Mr. SAYLOR says the State of Iowa refuses to give

a bounty, but exempts all beet-sugar investments from taxation for a series of years. Mr. Saylor approves this as a practical means of encouraging the industry. (590.)

B. Methods of sugar-beet culture.—1. **Improvement of the beet by artificial selection.**—Dr. WILEY says all the varieties of beets now used for sugar production have been developed by selection and cultivation from the *Beta vulgaris*, the original beet growing wild along the European shores of the Mediterranean. The beet in its wild state is an annual plant, producing seeds the first year, but when carried to the north of Europe it became a biennial plant, the seasons not being long enough to produce seed. That is the keynote of its success as a sugar-producing plant, because as soon as it begins to produce seed stems the store of sugar begins to be consumed, and the beet becomes pithy and woody and loses its sweetness very rapidly. The tendency to reversion is still very marked in the south of Europe; in France Dr. Wiley has seen as much as 5 per cent of the beets in a field producing seed, but this is not enough to very greatly interfere with the sugar content. In Germany probably one plant in 200 will produce a seed stem, but will not mature it. The general principle, true both in Europe and in this country, is that the farther north the beet can be brought to its first stage of maturity—that is, the stage at which it is ready to produce seed—the richer it will be in sugar, because (1) the cooler summers repress the tendency to seed production, and (2) there are longer periods of sunlight during the growing season. The finest beets grown in Europe are produced in Russia, and the farther north in Russia the beets will mature the higher the percentage of sugar. The sections having the longest days in the growing season are best adapted to produce beets. (639.)

Dr. Wiley says the development of the beet in sugar content has been accomplished by selection from beets grown in the usual way from ordinary seeds such as are planted for producing beets for the factory. Perfect beets are selected and carefully preserved in silos to protect them from frost. In the early spring the silos are opened and each beet subjected to a chemical analysis by boring diagonally through it, thus getting an average representation of that beet. If it contains less than 15 per cent of sugar, it is thrown away or used for cattle food. If it contains 18 per cent, it is very high grade. If it shows 17 or 16 per cent, it goes into other grades. The beets are then set back in the ground by grades. The boring does not destroy their vitality. There is still enough plant food to produce seed. These seeds are harvested and planted the next spring, and the second year there is another crop of beets with a general tendency to a high average grade, though some may be very inferior. By continuing this process from year to year a type of seed has been secured which will grow a commercial beet with an average of 15 per cent of sugar. The seeds could not be produced commercially from analyzed beets, as they would be worth \$5 a pound; but one mother will produce the second year a hundred beets, which, if planted, will produce seed enough to produce a whole field full. By this plan the sugar content of the beet has been increased from 5 per cent to an average of 15 per cent within the last hundred years, and the beets are still improving, but the limit has been practically reached. It is doubtful if richer beets can be produced unless a better grade can be obtained, as in northern Russia. The great effort is to hold the beet up to its high grade. The moment it is neglected it begins to degenerate. It tends to go back to the type of its ancestors, just as human beings do if opportunities for culture are taken away from them. All the high-grade seeds have been produced from analyzed beets in the fourth generation only, after the growth of 2 crops. The beet seeds sold by European seed growers are grown from the mothers produced 4 years ago and analyzed. (641, 642.)

Mr. SMITH says the beet seed is a thoroughbred, and represents generations of careful selection. The normal content of sugar in beets is perhaps 5 or 6 per cent, and yet beets are produced testing 18 and 20. Poor beets are thrown out, and only those kept for setting out the next year which test above the standard, say 16 per cent. That process is repeated 5 times at least before seed is put on the market, so strong is the tendency to revert to the normal content of sugar. (579, 580.)

2. **Seed farms.** (See also *Sugar-beet seed station*, —, p. —).—Dr. WILEY says there is no beet-seed farm anywhere in this country, though there are places in California where seed is grown in a haphazard way without analysis. If that is continued the content of sugar will run down, and the people who use the seeds can not compete with those who use high-grade seeds. The production of beet seeds requires the highest degree of skill and labor and the greatest amount of patience of any agricultural profession. The beet growers of Europe do not grow their own seeds, not having the necessary experience and ability, but buy their seeds of great farms devoted exclusively to seed production, such as that of Strandes, at Zehringen, where about 1,000 acres are devoted to the production of seed alone, and the still larger

Kleinwanzlebener farms. Practically all the beet seeds planted in this country are imported from Europe. The growing of high-grade seeds for commercial purposes would require a large investment, and it would be 4 years before it would yield any return. (642, 644.)

Mr. SMITH testified in May, 1900, that American seed had not yet been used on a commercial scale in Michigan, but that some of the imported seed was very unsatisfactory in 1899, and that a systematic effort would be made in 1900 to begin the growing of seed near the Alma factory. This industry would employ a great many men and demand the highest talent. (573, 579.)

Mr. Smith is convinced by the Nebraska experiments that American-grown seed acclimated to our conditions produce better results than foreign seed. The installation of a plant to grow beet seed is so very expensive and the returns so long deferred that people hesitate to go into it until the beet industry is firmly established; but Americans will be obliged to raise their own seed, for restrictions will undoubtedly be put upon the export of seed from Germany as soon as the industry is sufficiently developed in this country to be a menace to the sales of German sugar. (580.)

3. Preparation of soil and use of fertilizers.—Mr. SMITH says that to avoid leaving the soil bare during the winter, and to prevent consequent leaching, the farmers are urged to subsoil early in the fall, plow the ground, and sow some crop, such as rye or oats; this crop is inverted in the spring, replotting, and the ground put in perfect condition. This makes the expense of plowing and harrowing large, but the success of the crop depends largely upon the condition of the ground when the beet seed is sown. (576.)

Mr. ROGERS says the Binghamton Beet Sugar Company has provided the farmers with seeds and fertilizers, which they have paid for with the crop in the fall. A special high-grade phosphate fertilizer has been prepared for the purpose, carrying about 4 per cent of nitrogen, 8 per cent of phosphoric acid, and 10 per cent of potash, all available, and costing \$31. Most of the farmers have used about 400 pounds to the acre; where no manure was applied they used 800 pounds to the acre. (556.)

4. Planting and thinning.—Dr. WILEY says at least 20 pounds of seed should be planted to the acre, and more where there are bad conditions at the time of planting, because it is highly essential that the beets should be thick in the row to prevent overgrowth and inferior quality. There should be a beet every 6 or 8 or 9 inches in the row, and to do this a great many more seeds must be planted. Four or five seeds are wrapped up together, but on account of their highly artificial character they have a low vitality and a great many produce no sprouts. (643.)

Mr. ROGERS says in his vicinity beets are sown during May, and in about 10 days or 2 weeks after they are sown, when they are 3 or 4 inches high, they are cut out with a hoe and then thinned by hand.

Mr. Rogers has found it more profitable to cut out the beets with a hoe than with a cultivator, as it requires very careful work. Little clumps of beets are left 6 or 7 inches apart, the roots of which are wound around each other; someone has to put his thumb and finger on the beet to be retained, and pull up the rest with the other hand. The most successful beet raisers are foreigners who are not afraid to work; Americans do not like to go down on their knees. (555.)

Professor KEDZIE, of Michigan, explains that sugar beets are planted with drills, using not less than 20 pounds of seed to the acre. Part of the plants are removed by cross cultivation and careful thinning, leaving only a single beet once in 8 inches. The use of too little seed results in blank spaces, causing the overgrowth of the surrounding plants and a smaller percentage of sugar. (547.)

Professor Kedzie is of the opinion that American implements for cultivating sugar beets are better than those imported from Germany, excelling in lightness, finish, and efficiency; they have less draft and require less manual exertion. (547.)

Mr. SMITH says the foreign cultivators and seeders have been entirely discarded. The American implements, both within and without the factory, are superior to the German. With the Moline seeders and cultivators 4 rows are sown at a time and cultivated at a time, but that cultivator has been discarded in Michigan for one cultivating only 2 rows. (582.)

Mr. Smith says that to thin an acre of beets planted in rows 18 inches apart requires the work of an active boy or woman fully 6 days. It involves creeping on the knees $5\frac{1}{2}$ miles; taking two rows at a time does not lessen the time materially. It seems hardly possible to Mr. Smith that any machine can be invented to take the place of the human hand in thinning. (574.)

Mr. Smith considers the thinning of the beets absolutely unavoidable. The fruit which is sown contains from 1 to 4 seeds, and often produces 4 plants. The Michigan Experiment Station has experimented to find some way to avoid thinning, but without success; the fruit was carefully broken up into separate seeds, but the seeds do

not seem to develop well except in the fruit. Mr. Smith advises the farmers to use the hoe for cutting out the beets, instead of depending upon the cultivator. (575.)

5. Harvesting.—Mr. ROGERS says the beets are loosened with a lifter made for that purpose or dug with a subsoil plow or ditch plow, or plowed out with an ordinary reversible plow. The tops have to be cut off by hand. It is important to cut off the crown at the base of the lowest leaf, as the crown contains a large percentage of salt, which retards crystallization. By returning the crowns and leaves to the soil more than half the fertility taken out by the beet is returned. They also make an excellent food for cattle. (557.)

6. Necessity of intensive culture.—Mr. SMITH says the growing of sugar beets demands far more careful methods of husbandry than those to which American farmers have been accustomed. It requires better cultivation and fertilization and the expenditure of more money per acre. It thus broadens the minds and the methods of the farmers. (578.)

Mr. SAYLOR mentions, as the first difficulty which every new sugar factory has to meet, the conservatism of those who undertake to apply in growing sugar beets the experience gained in growing other entirely different crops. Growing sugar beets, he says, is intensive farming or gardening, the very highest type of field culture. (585.)

Dr. WILEY says growing sugar beets is horticulture rather than agriculture, and ordinary agricultural rules will not apply. The chief misfortune of beet culture in this country has been lack of knowledge on the part of the grower and sometimes lack of willingness to bend his back and crook his knees. It is hard even for an intelligent man, if he has never seen beets grown, to prepare the soil and cultivate the beets properly. (644, 665.)

7. Rotation.—Professor KEDZIE says:

"The sugar beet is an exhausting crop when the whole crop is permanently removed from the land, because it takes off a large amount of potash and phosphoric acid and much organic nitrogen; but none of these materials are removed in the commercial product—sugar—which contains only carbon, oxygen, and hydrogen, a pure carbohydrate, the carbon coming from the carbonic acid of the air and the oxygen and hydrogen from the rain. The sugar is essentially condensed or organized wind, water, and sunshine. No amount of sugar removed from the soil can reduce its crop-producing quality."

He adds that the fertilizing substances are found entirely in the leaves, crown, pulp, and molasses. If these are all returned to the soil, directly or indirectly, there is absolutely no reduction of the productive power of the soil, but an increase of fertility year by year. This is probably the reason why France has increased its wheat acreage from 17 to 28 bushels since the introduction of the sugar-beet industry. In Germany the farmers are not allowed to remove the leaves and crowns of the beet from the field. In both countries the sugar beet is considered the best possible crop to precede a crop of wheat.

Sugar beets make an excellent preparatory crop, because of the thorough and clean tillage required, which subdues the soil and keeps out the weeds. The leaves and crown of the beets should never leave the farm; the pulp should be converted into beef or milk by feeding to stock; even the residual molasses should be fed to stock. (539.)

Professor Kedzie says that any crop grown in continuous succession is exhausting to the soil. Sugar beets in successive crops are more injurious to the land than wheat, which is a surface feeder, because they have a wider range for feeding and exhaust the soil to a greater depth. It has been found in France and Germany that thorough rotation of crops is essential for the raising of beets. They should be grown only once in 4 years. Professor Kedzie recommends clover for securing a supply of atmospheric nitrogen, and barley or some other grain crop to precede the beets. (539, 540.)

Dr. WILEY says beets can not be grown on the same land more than once in 4 years; hence to supply a factory requires four times as much land as is necessary to supply it for any one year. A factory of 500 tons daily capacity will require 12,000 acres of land. (646, 652.)

Mr. ROGERS testifies that he planted 40 acres of sugar beets in 1899, on 20 acres of which beets had been grown the preceding year. The yield per acre in 1898 was 14 tons, and in 1899 between 10 and 11 tons; but he attributes the decrease to the extreme dry weather. (556, 557.)

Mr. TURNBULL states that it is found advisable in the growing of sugar beets to practice a rotation of crops, planting one-fourth or one-third of the land in beets every year. It is the common experience that other crops give larger yields when they are alternated with beets. They get the benefit of the deep plowing and thorough cultivation which the beets require. (979.)

C. Conditions and results of beet culture in America.—1. **Climate and soils suitable for beet culture.**—Mr. SAYLOR, in charge of beet-sugar investigations for the United States Department of Agriculture, says the beet-sugar industry in the United States is governed by conditions of climate, soil, and moisture. (1) A temperature of about 70° during the growing months is the best climatic condition, and sugar beets want about 100 days of good growing weather. (2) Beets are successful on two kinds of soil—those found in the Mississippi Valley, New York, and Michigan, where the fertility is due largely to their alluvial nature, and that found in the Rocky Mountain region and Pacific coast, which is rich in mineral matter. (3) In the Rocky Mountain region sugar beets are grown by rainfall and by irrigation; the plant is started by rainfall, but its further growth must be promoted by irrigation. In the coast country of California, where sugar beets are grown most extensively, they seem to depend upon receiving a supply of moisture by seepage from the rainfall of the winter; and a drought in the winter produces a shortage of the crop. In New Mexico beets are grown entirely by irrigation. (583.)

Mr. Saylor declares the idea that sugar beets need a light, sandy soil to be an error, due to the fact that the industry started in Nebraska, where the soil around Grand Island and Norfolk is really too sandy. The soil must be penetrable and fertile. The taproot goes down from 8 to 12 inches for its moisture, and soil underlaid with hardpan or tending to become compact, like hard clay or muck, is not suitable. The sugar beet, after it has four leaves, is a very hardy plant. After it has attained its growth the one thing needed is sunshine, the entire product of sugar coming from the atmosphere and being produced by the sunlight. (584.)

Dr. WILEY says a soil containing the ordinary elements of plant food is satisfactory for beets. The physical condition of the soil must be considered in beet growth, more than the chemical composition. The beet must have room to go down at least 16 or 18 inches in the soil, or it will be stunted and ruined; so the soil must be pervious. A stiff clay is not good for beets unless very heavily limed to flocculate it, so as to make it pervious and easily penetrable. Stiff clay soils are better for cereals that feed near the surface than for beets; but Dr. Wiley has seen very fine beets in Europe growing on heavy clay soils liberally limed. The soil of Michigan is very well suited to beet culture on account of its sand. It is a sandy loam that does not bake. The soil of southern California is mostly deposit soil which does not bake, but remains pervious. (649.)

Dr. Wiley submits a provisional map of the United States, showing the southern limit of probable profitable sugar-beet culture, following the isothermal line of 71 degrees for June, July, and August. The map was constructed on theoretical principles more than 10 years ago, but the lines would be practically the same if it had been made in 1900. (644-646.)

Dr. Wiley says California and Michigan are now taking the lead in the growth of sugar beets. In California where the coast winds keep the temperature down in the summer fine beets can be grown wherever water can be obtained. Michigan is peculiarly well suited for beet growth, as are also northern Indiana, Iowa, Wisconsin, and northern Ohio. All of central New York and portions of New England where the land is rich enough and level enough also grow beets. Fine beets are grown on the mountains all through North and South Carolina, but the contour of the land is such that an area of level land sufficient to supply a factory can not be obtained. Dr. Wiley has found one place in Maryland and West Virginia where enough land could be obtained and where a factory would prove very profitable. (646.)

New England.—Mr. ROGERS says the soil of the Connecticut River Valley, and of the White River Valley, when free from stones, is as well adapted to sugar beets as that of New York; but there are not enough acres of suitable soil to the square mile. (559, 560.)

Michigan.—Professor KEDZIE, of the Michigan Agricultural College and Experiment Station, testifies that by reason of soil, climate, peninsular position, and the intelligence and energy of the people, Michigan is well adapted to the production of sugar beets. The lands adjacent to the Great Lakes and the southern half of the peninsula are adapted to the raising of all crops and fruits suited to the climate, and the intermingling of many kinds of soil and the porous character of the deposit fit the soil especially for tuberous crops. The Michigan soils are rich in the ash materials required by sugar beets, and they are remarkably rich in potash, which is in special demand for this crop. The water capacity of 28 samples of soil from counties fairly representing the sugar-beet districts averaged 47.4 per cent, showing the ability of the soil to withstand drought. In passing over the Great Lakes the winds receive a moistening touch, and the average rainfall in central Michigan is 32 inches; along the shores of the Great Lakes it is a little more. The average rainfall is abundant in May, June, and July, when the sugar beet requires plenty of moisture, and there

is abundant sunshine in August, September, and October, the critical ripening months. (538-540.)

Mr. SMITH, director of the Michigan Experiment Station, says the broad alluvial Saginaw Valley is undoubtedly the most promising section of Michigan from the standpoint of the sugar-beet grower. The water table is within a few feet of the surface. The soil has an abundance of constituents, and is friable and easily penetrated by the growing roots, resembling somewhat the valley of the Platte in Nebraska. Much of the land lately given over to sugar beets was formerly devoted to truck farming and gardening, which fitted both the farmers and the farms for the economical production of beets. Other sections of the State, also, are well adapted to the industry, though near each factory there are many farms too sandy and light for beet production in dry years without a system of culture to maintain a surface-soil mulch, and too many of these farms were selected for beets in the dry season of 1899. There is within reach of each factory an abundance of soil well adapted to beets, and not all the desirable locations for factories are yet occupied. (567.)

Semiarid region.—Dr. WILEY characterizes the region lying between the humid and the arid regions as very treacherous. The conditions in Dakota and Nebraska are favorable to beet growth on the average, but almost the most pronounced variation of meteorological conditions in the world prevails there. Hot winds from the west wither vegetation, and in October there is sharp weather with snow. These rapid changes are unfavorable to beet growth, and although two of the oldest factories in the country are in Nebraska, if the operators were locating factories now they would put them somewhere else; though now and then they get an excellent crop. The conditions in Michigan and northern Ohio and New York are uniformly more favorable than in Nebraska. In these localities the best results are found. The contour of the land is suitable to beet culture, and the soil is reasonably fertile. Samples averaging 15 per cent sugar of reasonable purity for a whole season have repeatedly been received from these regions. (647.)

Beet growing by irrigation.—Dr. WILEY says an arid region where water can be obtained is the ideal place for beet culture, other things being equal, because of the sunny days and the absolute control of the water conditions. In the humid regions there is nearly always a September rain, followed by warm weather, and a second growth will take place, greatly to the detriment of the sugar, and the roads will become muddy and interfere with the harvest. Dr. Wiley predicts that the sugar beet will be the most profitable crop that can be grown on irrigated lands; it will pay fixed charges on land worth \$300 an acre, about what irrigated lands cost, whereas wheat or Indian corn would not pay the interest on the investment. (646, 647.)

2. Cost of production and yield per acre.—Mr. SAYLOR says it costs about \$30 an acre in almost any region to produce an acre of beets. The expense is mostly for labor. (584.)

Mr. SMITH, with the cooperation of a large number of Michigan beet growers, has calculated the average cost per acre of growing beets, exclusive of fertilizers and rent of land, as follows: Plowing (usually subsoiling), \$2.50; harrowing, several times, \$1; seed, \$2.50; sowing, 50 cents; cultivating, 6 times, \$2.40; thinning and weeding and hoeing, \$8; pulling and piling, \$6; topping, \$6; drawing (average 2.5 miles), \$6; freight (17 tons, at 20 cents), \$3.40; unloading, \$1.13; total, \$35.43. (575, 577.)

Mr. Smith estimates that the yield of sugar beets in Michigan was about 10½ to 11 tons to the acre in 1898, and 6½ to 7 tons to the harvested acre in 1899. A large acreage sown in the latter year was not harvested. The season of 1898 was very favorable, and the industry was confined to areas specially well adapted to the growing of sugar beets. The diminished yield is attributed to the unfavorable weather conditions and to the use of land ill adapted to the purpose. (565.)

Professor KEDZIE testifies that the average crop of sugar beets produced on the Michigan Agricultural College farm was 14 or 15 tons to the acre, with a sugar content of 15 per cent. The rate paid being \$4 for 12 per cent beets and an increase of 50 cents for every additional per cent, these beets would be worth \$5.50 a ton. The cost of raising them was about \$30 an acre, leaving a very nice margin. Professor Kedzie instances a farmer who raised 20 tons to the acre, and got \$90 an acre for his crop. (542, 547.)

Mr. ROGERS testifies that it would pay to grow even an acre or two of sugar beets. (562.)

Dr. WILEY says the average yield of beets to the acre is about 13 tons in Germany, a little over 11 tons in France, about 10½ tons in Austria, and a less amount in Russia. He estimates that the average yield in this country since the industry started would fall below 5 tons to the acre. He saw thousands of acres in California in 1899 that would not yield a ton to the acre; now and then a field will yield 20 tons. He would

consider it fortunate for American farmers if they can begin at 10 tons for an average. He thinks we shall do as well as Germany in time, but not for many years. Dr. WILEY attributes the lower yield in this country partly to drought and partly to carelessness in culture. (664, 665.)

3. Sugar content of beets.—Mr. SAYLOR says a growth of 2 or 2½ pounds is what a factory desires in a beet; if it exceeds that weight it is coarse in texture and inferior in purity. Hence the factory, in contracting with the farmer, always stipulates that the beets shall not exceed a certain weight, and shall have a specific sugar content and purity. (584.)

Mr. SMITH submits tables showing in detail the results of the analysis of sugar beets grown in the various counties of Michigan in 1897, 1898, and 1899. Where proper seed was sown on suitable soil in 1897 the average percentage of sugar was 16.4, far exceeding that of the best districts of France and Germany, and the average coefficient of purity 84. The results for 1897 were based on selected specimens, while those for 1898 and 1899 were based upon average specimens, making an apparent decline in the percentage of sugar. (563-566.)

Dr. WILEY says it costs no more to raise beets containing 18 per cent of sugar than those having only 16 per cent, except that a little more fertilizer may have to be used. It pays the farmer and certainly pays the manufacturer to try to get the largest percentage in the beets, because every additional per cent of sugar means a clear yield of 20 pounds more sugar to the ton, the amount of waste in manufacture being even less with a higher percentage of sugar. (664.)

4. Success of foreigners and Americans compared.—Mr. SMITH says the Michigan Sugar Company, the first company to build a factory in Michigan, was fortunate in having as patrons an agricultural community composed largely of Germans and Hollanders, many of whom were accustomed to raising beets in their native homes, and were therefore intelligent in their methods, besides working on a soil adapted to the beets. The season of 1898 was favorable in most respects, and the harvest was abundant and the financial returns exceedingly satisfactory. Mr. Smith submits as examples of intelligent management and good soils in a favorable season the results obtained by 10 farmers in that vicinity, showing profits ranging from \$18.85 to \$57.08 an acre. The more intelligent the application of fertilizers and the cultivation of a good soil, he says, the greater the yield. (568.)

Mr. Smith says most of the sugar-beet growers about Holland, Mich., are Hollanders who have had previous experience in raising either beets or similar crops; most of them raised beets in Holland. They have large and thrifty families, and are not afraid to get down on their knees and work. (578, 579.)

Professor DAVENPORT testifies that the production of beet sugar has been very carefully studied in Europe and well worked out by scientists, so that the most skillful sugar-beet growers the world has known are from Germany, but when they come into competition with Americans the American is able to beat them. In Illinois, in 1898, the best men in several different localities formed a temporary company, and employed an expert from Germany to tell them how to grow beets. The next year one of the largest sugar-beet factories was built at Peoria, and the farmers in the neighborhood grew better beets than this company could grow with supposedly expert beet tillers from Nebraska and Germany. (263, 264.)

D. Advantages of sugar-beet culture.—1. **Maintenance of fertility.**—Professor KEDZIE quotes Sir Humphrey Davy as stating that the continuous production and exportation of grain leads inevitably to the destruction of fertility, but says that nothing of this kind takes place in the production of sugar, because the sugar contains no elements of fertility. (540.)

2. **Influence upon agricultural methods.**—Dr. WILEY says the establishment of the sugar-beet industry in any locality is a blessing to all forms of agriculture practiced there, because it demands a scientific and just system of culture. Sugar beets can not be grown without fertilization; the crop demands the most careful nutrition in the soil. If any crop will teach the American farmer to increase the fertility of the soil, the sugar beet is that crop, and there is no farmer in the world who needs that lesson as the American farmer does. The introduction of the beet will bring about the feeding of the soil in this country more than anything else possibly could. (647, 648.)

Mr. SMITH predicts that the industry will ultimately be a success, and a benefit to the farmer. When the farmers realize that their harvest depends upon intelligent fertilization and management of the soil, when they have sufficient confidence in the industry to put the necessary fertilizers and work on the crop, and when they realize that the yield is not to be phenomenal, they will, on the average, have successful crops. The crop will pay well and be a great benefit to the State, and the by-products will increase the amount of live stock kept. (580.)

Mr. ROGERS believes the beet-sugar industry will do more than anything else toward lifting up agriculture, but the farmer must have encouragement, and must be educated in the production of the crop. (561.)

3. Benefit to the dairy industry.—Dr. WILEY says in the sugar-beet industry a vast dairy industry is built up around the factory; the pulps and other refuse fed to cattle make fine butter and milk; but cattle can not live in the Tropics, and dairies can not be established there with the refuse of sugar cane. (564.)

4. Effect on the labor market.—Mr. SMITH testifies that the establishment of sugar factories in Michigan exerted a marked influence on the labor market. Employment was given to men, women, and children who would otherwise have been idle, and the congestion of labor in the cities was less conspicuous than in former years. No serious disturbance of the labor market resulted; there have been times in all of the factories when labor was scarce, and exceptionally high prices have been paid, but on the whole there has been a fair supply to meet the demand.

During June and July and again in October the sugar factories give rise to an active demand for persons able to do light work, hoeing, thinning, and harvesting the beets. The supply of such labor has been insufficient near most of the factories. The thinning and hoeing comes for the most part after the close of the schools, and the topping is finished soon after the beginning of schools in the fall. The period of thinning and hoeing lasts about 40 days, beginning early in June. The lifting and topping occur in September and October, and the hauling to the factory continues into January. The plan of furnishing employment in the fields during the summer months to the men employed in the factory in the late fall and winter was projected by one factory for the season of 1900. At Alma in 1899 men were brought from Detroit to aid in thinning the beets. (574.)

Mr. Smith adds that the thinning must be done at just about the right time, or it is more expensive than it should be; and there is therefore an active demand for boys and women at that particular season and again at the season of harvesting. The Polish women about Bay City, adopting the American custom, when they saw the supply was limited, formed a combination and raised the wages. (575.)

Dr. WILEY says the beet factory employs all kinds of labor, from the commonest to the most skilled. He is not an advocate of the employment of women and children in the culture of the beet, as is done in Europe. He believes that it will be possible to do with machinery practically all that women and children do in Europe, and at less expense. The thinning of the beets must be done by an intelligent hand, but it is perhaps the only operation in the agriculture of the beet which machinery can not attend to. The cultivation, harvesting, and even topping of the beets (cutting off the leaves and upper part which contains the largest part of injurious salts) he believes can be accomplished by machinery, though handwork is almost universal in Europe. The expensive part of beet culture, however, will be the thinning. There must be skilled laborers in the factory. In Europe the field hand usually becomes the skilled factory hand during the manufacturing season. In this way the industry gives employment practically the year round; during the only months when there are probably no agricultural operations going on, the factories are in operation, either working up the crop or elaborating the molasses. This gives stability to labor and avoids the migratory condition which so often attaches to agricultural operations, as in grain harvests. It gives an individual interest to the labor on the farm and in the factory, and thus establishes a better morale among the laborers; a more efficient corps of laborers is secured, and the industry tends to advance socially and economically.

A factory of 500 tons capacity will require a corps of about 120 efficient laboring men the year round, on the farm and in the factory, not including those who make the machinery and build the factories and repair them. As the average family consists of 3 or 4 persons, the beet-sugar factory supports a laboring population approximately equal to the number of tons of its daily capacity, and it would require 400 or 500 factories of 500 tons each to supply our present needs. The labor required is the very best and the business is educating. In Europe other manufacturers want to get men who have worked in the beet factories. (652, 653.)

5. Certainty of a market.—Mr. ROGERS declares there is no other crop open to the farmer from which he can be assure of realizing the pay for his labor and use of land as from sugar beets, because his crop is contracted for before he plants it, and he knows exactly what he is going to get. The hardest thing with the average farmer is to dispose of his crop after he has grown it. (557.)

6. Effect on the price of land.—Dr. WILEY says that wherever the beet-sugar industry has been established in this country the value of farm lands has rapidly increased, because the beet is a more profitable crop than those previously grown. He is sorry to say that the fertility of the land has not increased in like proportion. (648.)

Mr. SMITH says the establishment of the Michigan sugar factories has appreciably

increased the selling price of farms in their immediate vicinity and near all railroad stations within 40 miles of each factory except that at Rochester. At Bay City there was at the date of his testimony (May, 1900) a greater activity in real estate transfers than for many years before, and the net advance in real estate values could not be less than 15 per cent, while one very large farm had sold for the purpose of growing beets at an advance of 50 per cent, and another at an advance of 25 per cent. Land rented for beet growing for from \$5 to \$8 an acre. (573.)

E. Relations of sugar factories to beet growers.—1. Prices paid for beets.—Mr. SMITH says the price paid the farmer for beets depends upon the percentage of sugar in the beet, which in Michigan is determined by an analysis made at the factory by men appointed by the State. (581.)

Dr. WILEY says it is usual throughout this country to base the contract upon 12 per cent of sugar, with so much increase for each additional per cent; thus the farmer has a direct interest in growing beets with a high percentage of sugar. The high percentage is secured largely by using high-grade seeds and planting very thickly, so as to prevent the beets from exceeding a pound in weight. This same custom is practiced in most parts of Europe also, but in France beets are bought at a flat price. Wherever that has been practiced the tendency has always been to have a low grade of beets. The higher results have been secured only where the beets are paid for by the quantity of sugar they contain. (604.)

Mr. SMITH says one result of the adverse season of 1899 was a pressure upon the factories for a higher price for beets and for other concessions. The factories yielded to this pressure and raised the price for 1900 to \$4.50 a ton for 12 per cent beets, with an addition of 33½ cents for each additional per cent of sugar. (577.)

2. **Tare and marc.**—Professor KEDZIE says the most successful of the Michigan factories has been that of the Michigan Sugar Company at Essexville, near Bay City, which was first in the field and has been very wisely managed. There has been less friction with the farmers there than anywhere else. The manager gave directions that when questions arose the farmers were to be given the benefit of the doubt. There are two points in the relations of farms to factories where friction may arise: (1) tare, or reduction from gross weight as allowance for adhering dirt and insufficient removal of the crown of the beet; this is left much in the hands of weighmen, but is open to the direct inspection of the farmers, and some of the factories have offered to let the farmers elect their own weighmen; (2) marc, or deduction from the amount of sugar found in the beet juice for nonsaccharine solids, in order to determine the actual amount of sugar. The marc adopted by the chemical division of the Department of Agriculture, and generally agreed to by chemists, is 5 per cent, but a factory may select an arbitrary marc or use the unreliable alcohol method in estimating it. Professor Kedzie is informed that one factory has adopted a deduction of 16 per cent for marc. (544-546.)

Professor Kedzie says the question of cooperation of the farmers with the factories by agreeing to furnish beets and receive such a proportion of the product has been discussed. He thinks that if this could be carried out it would prevent strife. He thinks this system of cooperation has been tried very thoroughly in Germany. (546.)

Dr. WILEY says the beet is 95 per cent liquid (including solids in solution) and only 5 per cent insoluble solids. The insoluble matter (fiber or pith) is called marc, a French word which came into use with the French method of analysis. Polarization determines the amount of sugar in the juice, and if the juice represents 95 per cent of the weight of the beet, the proportion of sugar in the beet is ninety-five one-hundredths of the percentage in the juice. As beets are sold by the percentage of sugar they contain, it is important that a fair method of computing marc be agreed upon. The usual custom in this country has been to use the factor 0.95, assuming 5 per cent of insoluble matter. Dr. Wiley thinks this a fair rule, but there are variations in the marc. If the beet is grown at an exceptionally dry time, if it is exceptionally ripe, or if it contains a second growth, the tendency is to increase the percentage of marc. If the beet produces seed, almost everything left is insoluble. To establish a factor so abnormal as 0.88 and apply it to a normal beet, however, is unscientific and unjust. The advocates of a higher marc than 5 per cent state that in extracting sugar in alcohol (the uniform custom in this country) the marc is sometimes 8, 10, or 12 per cent; but alcohol dissolves sugar with great difficulty, and when the extraction is continued only the ordinary length of time a considerable percentage of the sugar is not extracted. There is another method of determining the percentage of sugar in the pulp without expressing the juice—by aqueous diffusion. By using a peculiar form of rasp an impalpable pulp is obtained, in which the cells have been ruptured. When this pulp is mixed with water the sugar content passes into solution and is polarized. This method has come into general commercial

CCLXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

use in France in the past decade, and gives the correct percentage of sugar in every case. This method has been used in the laboratory of the Department of Agriculture. Dr. Wiley strongly advises its introduction for commercial purposes, especially under abnormal conditions, if the friction continues between the factories and the farmers. There were abnormal conditions in Michigan in 1899, and in many cases the marc may have amounted to 8 per cent, though that is hardly likely unless there was a second growth. In some instances factories may have had a just ground for increasing the marc, but it would be very unfair to apply the increase another year when the beets are normal. The actual percentage of marc for the normal beet is a little less than 5 per cent, so that in taking 5 per cent some concession is made to the manufacturer, and the farmer is in favor of letting it go at that. In Michigan, where the manufacturers were contending for 7 per cent and Dr. Kedzie and others for 5 per cent, Dr. Wiley finally said he would be willing to compromise at 6 per cent, but he considers this a little too high. To make the marc 14 per cent he characterizes as robbery, because such a condition would never occur in any field of beets. (662, 663.)

Dr. Wiley says the wise manufacturer will concede to the farmer a little more than may be just in order to help establish the industry properly; without successful agriculture nothing is possible. (664.)

Mr. SMITH says the Michigan Sugar Company and most of the Michigan factories accept 5 per cent as the normal marc, but the Alma and Bay City companies calculate it at 8 per cent, and in the western part of the State some of the factories have used as high as 10 or 12 per cent marc in dealing with individual farmers. This has caused a great dissatisfaction among farmers about Holland and Benton Harbor, and some have absolutely refused to raise beets. (571, 572.)

Mr. Smith says that in some of the factories the growers will nominate the tare men, and possibly have some voice in the selection of the weighman and beet tester, thus removing all grounds of suspicion except in the matter of marc. (578.)

Mr. TURNBELL states that each load or car of beets delivered to the American Beet Sugar Company at Oxnard, Cal., is tested for the percentage of sugar, and the farmers are allowed to employ a check chemist to verify the tests. (579.)

3. Beet growers' associations.—Mr. SMITH testifies that the beet growers about Bay City have organized an association for mutual instruction in the art of beet growing and for the purpose of securing better prices. The association was formed in the late summer of 1899, and held frequent meetings during the winter and spring. It was this organization which secured the increase in the price of beets. Similar organizations are formed for the western part of the State. (577, 578.)

4. Assistance to farmers.—Mr. ROGERS testifies that the Binghamton Beet Sugar Company the first year employed 4 men in the field all summer to instruct the farmers and get a complete history of every man's crop. This made it possible to tell the kind of soil and cultivation best adapted to sugar beets. (561.)

Mr. TURNBELL testifies that the American Beet Sugar Company, of Oxnard, Cal., furnishes the seed at cost, 12 cents a pound, deducting the amount from the first delivery of beets. The company also employs a number of agricultural experts, and advertises to give the growers the benefit of their knowledge as to the proper handling of the land, planting, thinning, harvesting, etc. (579.)

5. Transportation, storage, and pitting.—*New York.*—Mr. ROGERS says beets are hauled to Binghamton from distances of 75 to 100 miles. The season for running beet-sugar factories is about 100 to 120 days, beginning in New York the 1st of October. The Binghamton Beet Sugar Company provides storage sheds for the beets, all of which are received by the 1st of December. The factory has a capacity of 250 tons per day of 24 hours. It handled 13,000 tons in 1899, and contracted for about 20,000 tons for 1900. (553.)

Michigan.—Mr. SMITH says over 50 per cent of the beets are hauled to the factories on cars from stations up to 40 miles from the factory. Some factories pay the freight on the beets, and in some cases they are unloaded free of cost; in other cases the beets are received at any time, and the farmers not forced to pit them. (577, 578.)

Mr. Smith emphasizes the difficulty of the storage problem. Most farmers prefer to hold the beets and deliver them after the harvest. During the harvest they have large gangs of men, and they want to devote all their energies to getting the beets pulled up and pitted, hauling them to the factory at their leisure during the winter. It seems inevitable that the farmer must deliver his products in installments as called for by the factories, because of the bulkiness of the crop and the limited capacity of the beet sheds which a factory can construct. To keep the beets from thawing after freezing they must be buried, and the cost of pitting them and afterwards removing them from the pit with pick and shovel has deterred many farmers from beet growing. To obviate this difficulty the Benton Harbor factory undertook in 1900 to

receive beets as fast as farmers could deliver them or to pay the expense of pitting. (576-578.)

6. Cooperation and collective ownership.—Dr. WILEY declares that the interests of the manufacturer and farmer are identical. If a manufacturer wishes to get the advantage of the farmer, he is cutting his own throat, and the farmer who wants to get the best of the manufacturer is defeating his own interests. Success is a benefit to both. These things have adjusted themselves in Germany largely through cooperation. About one-half of the beets grown in Germany belong to farmers who have shares in the factories. In the year 1894-95 the area under cultivation was 1,090,801 acres, or 441,441 hectares. The yield of beets was 32.9 tons per hectare, or 13.3 tons per acre. Of this crop 41.64 per cent was grown by the factories and 58.36 per cent was bought by the factories. These percentages vary slightly from year to year, but represent very closely the relative magnitude of the cooperative beet growth as compared with the total magnitude of the industry in Germany. Dr. Wiley says it is evident that if such a system of cooperation could be established in this country it would be very much more satisfactory both to the farmers and to the factories, inasmuch as the former would be factory owners. He believes that in the course of time the cooperative factory will be a very large element in the industry in this country, and that it is the best solution of the difficulty, though it is a little hard on outside farmers, because the cooperative factories pay a very low price for beets. In Germany all the cooperative factories pay less for beets than the noncooperative factories. (663, 664.)

Mr. SMITH says a large share of the stock of the Holland Sugar Company is owned by farmers in the vicinity of Holland. (572.)

F. Manufacture of beet sugar.—**1. Number and capacity of factories.**—Dr. WILEY submits a list of the 30 beet-sugar factories in operation in 1899, showing a total capacity of 19,100 tons daily, of 6 factories building in May, 1900, and of 5 other companies organized and having factories projected either for 1900 or 1901. The factory at Crockett, Cal., refines the Hawaiian sugar in addition to its local business. Most of the factories have a capacity of about 500 tons. Dr. Wiley explains that the capacities given are maximum capacities, which are rarely reached, because with the complicated machinery there is seldom 24 hours of uninterrupted work. The real working capacity may be estimated at about two-thirds of the maximum capacity, or between 12,000 and 15,000 tons daily. The probable yield in 1899 was about 65,000 or 70,000 tons. Dr. Wiley estimates the production for 1900 with a favorable crop at nearly 100,000 tons. (650-652.)

Dr. Wiley says the average size of our factories is larger than in Europe. The largest factory in the world is at Salinas, Cal., with a capacity of 3,000 tons of beets daily. The factories are operated only from 60 to 120 days a year. (640.)

Mr. ROGERS thinks that sugar can be made at a minimum cost in a factory with a capacity of 500 tons a day. The cost of a 500-ton plant is about \$500,000. (558, 559.)

2. Location of factories.—Mr. SMITH says that in selecting sites for beet-sugar factories it was necessary to consider not only the attitude of the farmers and the quality of the soil, but an abundant and pure water supply and transportation facilities, upon which depends the cheapness of coal and limestone. (567.)

Mr. SAYLOR says that on the Pacific coast the beets are planted in some places in February. Some of the factories are so fortunately located with reference to the variance in the time of harvesting in the surrounding valleys that they have a long time for the manufacturing campaign, beginning as early as August. In the Mississippi Valley, Michigan, and New York the harvesting begins about the middle of October and is done all at once. (583.)

Mr. WHITNEY says two sugar factories have been closed within the last 2 or 3 years, because located on lands containing alkali. (869.)

3. Employment of experts.—According to Mr. SAYLOR, business men know nothing about the process of making sugar, and very little about the markets for sugar. They must depend upon an expert in manufacturing until experience has given them the necessary information. (586.)

Mr. SMITH says that while it was necessary at the outset to employ experts from abroad, Americans are rapidly learning the business, and the American factories will soon be manned throughout by Americans. The employment of foreigners as laborers and as superintendents has not been entirely satisfactory. The West Bay City factory imported a large number of Bohemians and Austrians in 1899, but they were shipped back to Europe at the close of the campaign. Several of the Michigan factories were planning to employ American labor almost exclusively in 1900. (570, 571, 573.)

Mr. SAYLOR says there are two factories in California where foreigners accustomed

CCLXVI THE INDUSTRIAL COMMISSION;—AGRICULTURE.

to the labor are employed, but the rest of the work is done largely by Chinese and Japanese. (590.)

4. American and imported machinery.—Mr. ROGERS testifies that the machinery used by the Binghamton Beet Sugar Company is partly French and partly American. There is a duty of 45 per cent on the imported machinery. Some manufacturers in this country have been making as good machinery as can be made in France, but some German concerns make as good machinery as is made in this country. (558, 559.)

Mr. Rogers testifies that the sugar factory at Rome has ceased operations, the proprietors having bought a plant in Canada; but a company was organized at Lyons, Wayne County, in the spring of 1900, which took the contracts that formerly had gone to Rome. The foreign machinery used in the Rome factory was very unsatisfactory. It took 105 days to work up 9,000 tons of beets. (558.)

Professor KEDZIE says the machinery for the manufacture of beet sugar made in the United States is unquestionably better than the German machinery. The factories at Essexville, near Bay City, at Rochester, and at Alma are equipped with American machinery, and have turned out sugar of most excellent quality. (543, 544.)

One manufacturer, however, used German machinery and employed a German chemist, producing some very miserable sugar, which injured the general confidence in the Michigan product.

Mr. SMITH, director of the Michigan Experiment Station, testifies that the sugar made in the 9 Michigan factories in 1899 was generally a prime article, but at the date of his testimony (May, 1900) there was a lawsuit pending between one of the companies and the builders of its factory, who had put in German machinery adapted to the manufacture of sugar for refining purposes and not for the market. The president of the company had succeeded in selling the sugar to refining companies and elsewhere to very good advantage, so that the financial loss was not very great, but unfortunately much sugar was sent to Chicago which was off color, and the people who had formerly bought the product of the Michigan companies without question at once became suspicious, and would buy no sugar from Michigan without examination. The reputation of all the Michigan factories suffered from the output of this one factory. (569.)

Mr. Smith says the West Bay City Sugar Company has suffered great financial loss because the German machinery in its factory was not capable of extracting the proper amount of sugar. The beets yielded only 124 pounds of sugar to the ton of beets for which the factory paid an average of \$4.33½ a ton. (570.)

Dr. WILEY says the United States is still far behind in the culture of the beet, though we have the best beet-sugar factories in the world and experts are coming from all over Europe to study them. Our constructors are quicker to adapt themselves to exigencies than the European machinists, and have made better machines, a great many of which are now being used in Europe, especially the centrifugals, or drying machines, which are recognized everywhere as the best in the world. The first American factories imported every piece of machinery they contained, but some of the best factories in this country to-day have no imported machinery; though some forms of machinery, such as the slicers, are still imported to some extent. The boilers, centrifugals, evaporating pans, vacuum pans, and driers are all of domestic manufacture. Dr. Wiley is informed that one of the factories equipped almost entirely with imported machinery for the crop of 1899 and 1900 replaced it with American machinery for the crop of 1900 and 1901. (640.)

5. Extraction of juice.—Dr. WILEY says that in making the analysis to determine the amount of sugar in the beet only a portion of the juice is extracted, but the juice which remains has practically the same composition. No machine will express all the juice; an ordinary press will not take out more than 50 or 60 per cent. That is the reason the press can not be used in commercial operations, as in the case of sugar cane. A good strong sugar mill properly adjusted will take out from 80 to 82 per cent of the juice which the cane contains, but no press will extract that much juice from the beet. (602.)

Mr. SMITH submits a table showing for each of the 9 beet-sugar factories in Michigan the quantity of beets sliced and the amount of dry granulated sugar produced in 1899. The product varied from 124 to 182.1 pounds of sugar to the ton of beets.

Mr. Smith says the construction companies claim that their factories ought to extract 10 per cent of sugar, or 200 pounds to the ton, but Mr. Smith has never been in any factory east of California that claimed to get as much as that, and the Michigan factories come very far short of it. The Michigan Sugar Company, in order to get 182 pounds, had to modify the temperature in the diffusion batteries in a way the German operators knew nothing about. (569, 570.)

Mr. Smith explains that the amount of sugar reported refers to the amount of crystallized A No. 1 granulated sugar. There is also some second and third run sugar which reduces the loss somewhat. Mr. Rogers says the second and third run is not obtained in most of the Michigan factories. Mr. Smith thinks the percentage of sugar recovered will increase. (581.)

6. By-products.—Pulp.—Mr. SAYLOR says there is no feed known equal to beet pulp for dairy cows and for fattening steers, or for sheep, lambs, mares, and hogs; but few farmers appreciate its value and few of the factories are able to realize much from it. In California whole dairy districts, running train loads of milk into San Francisco, have been established solely because of ability to secure this pulp at a price of \$1 a ton. (587.)

Mr. ROGERS says that the Binghamton Beet Sugar Company at first gave the pulp to the farmers, but after about a month charged 25 cents a ton, and only a small part of the product was taken. In 1899 the company charged 50 cents a ton and could have sold three times the amount produced. Mr. Rogers has found 60 teams in line waiting to be loaded, and many of them would wait all day. The company now gives beet growers special accommodations for getting pulp. Mr. Rogers says the pulp is one of the best milk-producing foods he knows of, and is worth more than \$1 a ton to any farmer who has dairy cows to feed. Some farmers have paid that much freight on it. (554.)

Professor KEDZIE says that in Michigan the pulp was at first given away to the farmers, and the factories even ran it out on cars so as to dump it into the farmers' wagons. At Bay City they are trying to form a company for drying the pulp so that it can be carried to a distance and sold as cattle food. Professor Kedzie thinks the farmers of Michigan have been sufficiently awakened to the value of this pulp in connection with other food for fattening stock. In Nebraska it has been used very largely for feeding stock, and the most delicious and juicy beef has been made out of pulp and prairie hay. The pulp also increases the flow of milk. It can be siloed and will keep better than common corn ensilage. (548.)

Mr. SMITH says the supply of by-products at Bay City is so large that only a small percentage is utilized for feeding live stock and for fertilizers, but he has found a growing feeling among the farmers in that vicinity in favor of feeding the pulp to cattle, and many teams were engaged up to late in the spring of 1900 in hauling it away. Farmers were preparing to make ensilage of it, and relied upon it largely as succulent feed for dairy cows and pigs. The molasses, rich as it is in potash, is never wasted in Michigan. The slaked lime is being used as fertilizer on lands needing it near all the factories. (573.)

Mr. Smith, testifying in May, 1900, said the Bay City Company was installing a plant for drying the pulp and mixing it with molasses to make feed for cattle. The bulk of the product was already sold for export at a nominal advance over the cost of production. It contained 16.9 per cent of protein and a high percentage of carbohydrates. (571.)

Mr. SAYLOR says that in Germany the pulp is dried and prepared for the market as flax-seed meal and other products are in this country, and sells in the feed stores for about 60 per cent of what these products bring. (586.)

Mr. TURNBULL, of California, states that both the beet tops and the pulp are valuable food for sheep and cattle. A yield of 15 tons of beets to the acre leaves 6 or 8 tons of green tops on the field, and the company gives the grower half the weight of his beets, $7\frac{1}{2}$ tons, in pulp, at 10 cents a ton, on cars at the factory or on wagons at the factory loading chute. Mr. Turnbull presents a table giving the value per ton and the value per acre of beet pulp, beet tops, alfalfa hay, barley, barley hay, and barley straw. The value per acre of the beet pulp and tops together is given as about \$25, while the value per acre of a crop of barley hay is given as \$18, of a crop of barley, grain and straw together, \$27.75, and of alfalfa hay \$48. The beet tops are best utilized by bringing cattle or sheep upon the fields as soon as the beets have been carted away. The droppings remaining on the land contain nearly all the mineral plant food of the tops. (979, 980.)

Molasses.—Mr. SAYLOR says that in Europe alcohol, vinegar, and shoe blacking are manufactured from the molasses, but in America thus far it is a loss. One of the problems to be worked out is that of extracting the actual sugar from the molasses, giving it a greater value than it has as a by-product. (587.)

Dr. WILEY submits a statistical table showing Germany's production, importation, utilization, and exportation of molasses since 1871, and a statement explaining the various processes employed. (657.)

Mr. ROGERS says that in 1899 he began distributing molasses to the best farmers, and it was fed to cattle and horses with excellent results, by pouring it on the hay or grain. The molasses is about 50 per cent sugar and 5 per cent potash, and is very

CCCLXVIII THE INDUSTRIAL COMMISSION;—AGRICULTURE.

fattening. In Germany much of the molasses is made into alcohol, but less than formerly because it is used as a food product. The Binghamton company can not afford to make it into alcohol and pay a tax of \$2.10 upon it. It is rated as grain alcohol; if it could be put in as wood alcohol, on which there is no tax, the company could afford to make it. (554.)

7. Branch factories.—Mr. SAYLOR says the factory at Lehi, Utah, has established a substation known as a rasping station, where the juice is extracted from the beets and pumped to the central factory through a pipe line 30 miles long. A second substation nearly as far away was being established in the spring of 1900, and several pipe lines were contemplated in case these should prove successful. Mr. Saylor says the success of these experiments would tend to revolutionize the sugar industry, making it possible to locate a factory at some point favorable on account of its facilities for fuel, shipping, water, etc., and subfactories at other points, thus bringing them into close relations with the farmers. (585, 586.)

G. Sugar cane.—**1. Production.**—*Louisiana.*—Dr. WILEY says we use in this country 2,000,000 tons of sugar yearly, and produce about 300,000 tons of all kinds. The Louisiana production fluctuates greatly, averaging probably 200,000 tons. In the winter of 1898-99 the temperature fell to 13 degrees, practically killing all the cane in the State. Louisiana is not far enough south for cane sugar, and is entirely too far south for beet sugar. Texas has produced cane sugar, but its production is unimportant. Florida is hardly to be considered as a cane-sugar country, at least until the swamp lands are drained. Dr. Wiley thinks the production of cane sugar in the United States is more likely to decrease than to increase. Cane is now planted in Louisiana practically every 2 years; in Cuba it is planted once in 15 years, and fields are frequently harvested for 50 years. (649.)

Dr. STUBBS estimates the sugar-cane production of Louisiana for 1901 at 300,000 tons, though he says it should have been 400,000 tons. The crop of 1897, the largest ever made, was over 340,000 tons; but the crop of 1898 was damaged by a very wet fall and that of 1899 by a very destructive frost. (772.)

Mr. SAYLOR testifies that the cost of producing sugar in Louisiana is considerably higher than in the tropical islands, Cuba, Hawaii, and Porto Rico being more natural cane producers, and wages being higher in Louisiana. (589.)

Cuba.—Dr. WILEY declares that Cuba is the natural sugar-producing country of the world; that no other country can compare with it. He prophesies that if Cuba is prosperous and has a suitable government it will in 50 years produce 3,000,000 tons of sugar a year, but first immense forests must be subjugated, railroads built, and marshes drained. As Cuban sugar comes in German sugar will stay out. The maximum production of Cuba in the past has rarely exceeded 1,000,000 tons. In 50 years the United States will eat at least 6,000,000 tons of sugar yearly, so that there will be the same necessity for domestic production that exists to-day, even allowing for the most favorable development in the tropical regions. (653.)

Hawaii.—Dr. WILEY says Hawaii also is a garden of cane, but nature has prevented any great expansion, and practically all the land in the Hawaiian Islands capable of growing sugar is under cultivation. In the yield per acre Hawaii exceeds Cuba; an almost incredible yield of 14 tons of sugar to an acre of land has been obtained. (654.)

SAYLOR testifies that the leading plantation of the Hawaiian Islands produces 10.1 tons of sugar to the acre, a larger average than some States make from beets, but for all the islands the average is about 5 tons to the acre. (589.)

British possessions.—Dr. WILEY says that though the British are better farmers than the Spanish they have never been able to compete in their West Indian possessions with Cuba in producing cane sugar, and to-day the sugar industry in the British West Indies is bankrupt. The West Indian Commission thoroughly investigated the question, with the result that the home government gave several hundred thousand pounds to keep the industry from becoming exterminated. If necessary, science with the sugar beet can destroy the natural sugar plant of the Tropics. (654.)

Dr. Wiley says that, with all the agricultural skill of the British and their fertile lands in the Barbadoes and British Guiana, their sugar industry has gone to the wall in competition with the beets of Europe. Dr. Wiley suggests that at some future time Hawaii and other cane-producing countries may also feel the effect of this competition. (654.)

2. Methods of cultivation.—Dr. WILEY says sugar cane is not susceptible of scientific improvement, as the beet is, though it can be improved a little by selection. Cane is produced to a limited extent from seed, but the joints of cane so produced are planted just as the old cane is, and the possibilities of improvement in that manner are limited. (653, 654.)

Dr. STUBBS says triennial rotation is usually adopted in Louisiana. The land is first planted in corn and laid by in cowpeas. The cornstalks are cut, and the peas are plowed under with large 6 or 8 horse plows and the land immediately put in cane, which is planted in September, and from that time until March. The stubbles are allowed to bear another year. At the end of the second year the land is plowed and put back in peas, which give a nitrogenous crop of 120 to 125 pounds to the acre, thus supplying the fertility of the soil. Some planters, particularly in the extreme southern part of the State, employ a quadrennial rotation, leaving the fields in stubbles 2 years. A few great sugarhouses make "succession cane" (that is, they plow up the cane and plant again at once); but only when they require all the cane their lands will produce. This practice is extremely wearing to the soil, because the cane is a great nitrogenous crop. (774.)

3. Sugarhouses.—Dr. STUBBS testifies that the sugarhouses of Louisiana represent an investment of \$100,000,000. They are up to date in every respect, and fully equal to any in the world, not excepting those of Hawaii. Dr. Stubbs believes that the full equivalent of the profits made in the sugar industry in Louisiana since the war has gone into the reconstruction of these sugarhouses, in order to increase their capacity and diminish the expense. Sixteen years ago a sugarhouse with a capacity of 200 tons of cane a day was considered a marvel; now several take from 1,500 to 2,000 tons a day. It formerly required 40 or 50 hands to put the cane on the carrier in a mill of 200 tons capacity, but now the whole wagonload of cane is lifted by machinery into cars that are run alongside the carrier. Thus 2 or 3 men will feed the carrier with 1,500 or 2,000 tons a day.

The sugar interests of Louisiana have been economized by increasing the capacity of the sugarhouses. A sugarhouse with a capacity of 1,500 tons of cane daily can produce sugar much more cheaply than one of 200 tons capacity, because the same amount of intelligent expert labor is required in either case. The vacuum pan, discharging 300,000 pounds of sugar daily, can be operated by one man just as easily as the one at the experiment station, where only 2,500 pounds are produced. Improved machinery has saved the sugar industry. (771.)

4. Molasses from cane sugar.—Dr. STUBBS says that until a few years ago the molasses from the sugarhouses which exhaust the sugar had no sale, and was thrown into the streams. The introduction of tank cars has made it possible to realize a profit from the molasses. The tank cars are brought up to the sugarhouses and the molasses pumped into them and shipped to Chicago, Toledo, Buffalo, and elsewhere, to be mixed with glucose and sold as molasses. One barrel of Louisiana molasses and 3 barrels of glucose make 4 barrels of nice Louisiana sirup, and Louisiana imports almost 3 times as much glucose as is sold of the finished Louisiana molasses.

A great deal of the molasses is fed to stock. It is worth more as feed than the commercial price of 3 to 5 cents per gallon, but the planters make from 3 to 5 times as much as the stock can consume.

In the open-kettle sugarhouses, where probably one-fifth of the product of the State is still made, after evaporation in an open vessel, the sugar is clarified very thoroughly and put into hogsheads and drained, the drainings constituting open-kettle molasses, worth from 30 to 50 cents a gallon unadulterated, or \$1 a gallon when mixed with white glucose. The great demand for this molasses keeps alive the open-kettle sugarhouses.

The molasses, after being mixed with glucose, sells throughout the country as Louisiana sirup, and goes into retail consumption for eating. Upon analysis it is easily detected, because glucose is a right-polarizing sirup, and mixed molasses frequently polarizes 104 to 105, whereas the maximum for pure sugar is only 100, showing that it contains corn sirup, which consists of glucose, maltose, and dextrin, all 3 of which polarize heavily to the right, making the polarization of the mixture to the right larger than that of sugar. (774, 775.)

5. Louisiana sugar planters.—Dr. STUBBS says the sugar planters of Louisiana are perhaps the most intelligent body, as a rule, in the world. They are wealthy, thoroughly educated men—a cosmopolitan people who came to Louisiana and invested their capital in sugar plantations. While they were educated in many lines, they were not all well advanced in sugar methods, and early felt the necessity of information of that kind. (781.) (See also *Sugar experiment station*, E, p. cxxvii.)

Dr. Stubbs says the profitableness of the sugar crop depends largely upon the man managing it. There is more in the man than in the land. The economical and intelligent administration of a good sugar estate frequently brings profits where other estates fail. (773.)

H. The maple-sugar industry in Vermont.—Mr. SPEAR, manager of the Vermont Maple Sugar Association, testifies that out of 50,000,000 pounds of maple

sugar produced in the United States, the census credits Vermont with 15,000,000 pounds. New York produces the next largest amount, and Ohio produces about 6,000,000 pounds. Some 22 or 25 States produce more or less maple sugar. The industry means to the Vermont farmers an income of from \$1,000,000 to \$1,500,000 a year, and is as important to them as any line of industry they are engaged in, except dairying. The income from sugar is practically so much added revenue. The sugar season of about 3 to 6 weeks comes at a time when there is not very much else to be done. The sugar-making season is a time of considerable social interest. Nearly every sugar camp has its sugar parties of young and old. The maple groves are used for pasturage to a considerable extent; the growth of maple trees does not prevent the production of considerable feed for stock. New orchards have been planted in a few sections, and this ought to be done more. They mature sufficiently to be utilized in 35 to 40 years. A great many trees have been planted by the roadside, serving for shade as well as for sugar. The average product of a maple tree varies from 1 to 5 or 6 pounds; 3 pounds is a fair average. It is not advisable to have more than 30 or 40 trees to the acre. When they are 50 years old the product should be about 100 pounds of sugar to the acre. The price varies from 5 to 15 cents a pound.

Mr. Spear says the maple-sugar industry has undergone great changes in the past 40 or 50 years. The sap used to be boiled out of doors in a caldron kettle, where charcoal and leaves could get in. Maple sap is almost as susceptible of contamination as milk, and the best operators now handle it with as much care. If it is exposed to the air it loses its delicate flavor and its light color. It is evaporated in sugarhouses immediately after being drawn from the trees. It takes about 10 or 15 minutes for the sap to flow from one end of the evaporator to the other, and it should be boiled rapidly enough to be drawn as sirup when it reaches the farther end. A large amount of sugar, however, is still made carelessly and exposed to bad atmospheric conditions. (405-407.)

1. Commercial aspects of the sugar question.—1. World's production of sugar.—Dr. WILEY testifies that the world's production of sugar is probably 7,000,000 tons, of which more than 4,000,000 tons are produced from beets, practically all on the continent of Europe. (638, 639.)

2. Consumption in the United States.—Mr. SNOW testifies that the annual consumption of sugar in the United States is about 4,000,000,000 pounds, or 2,000,000 tons, of which nearly 1,700,000 tons are imported. (241.)

Dr. STRUBBS says rice and sugar can not be overproduced for years to come. The sugar crop is only one-seventh of the country's consumption. Our present consumption of sugar is a little over 2,000,000 tons, of which only about 300,000 tons are produced in Louisiana. (773, 782.)

Mr. ROGERS says the consumption of sugar in this country is about 80 pounds per capita, and is increasing every year. Three-fifths of all the sugar we are now consuming (May, 1900) is beet sugar. (562.)

Dr. WILEY says the consumption of sugar per capita in this country is between 62 and 65 pounds. In England it is between 72 and 75 pounds. The consumption is greatest in England, a great deal being used for preserving jams, marmalades, etc., largely for exporting. The consumption on the table is greater per capita in this country than in England. (650.)

Dr. Wiley says the United States is now consuming 2,000,000 tons of sugar, and predicts that in 10 years the consumption will be 3,000,000 tons. If the sugar from our 2 tropical possessions were brought in free there would still be a shortage in the supply, and it would take years to reestablish the industry in Cuba and the Philippines to anything like its former extent. It will be necessary to continue the importation of beet sugar from Europe or to extend our own industry. Dr. Wiley believes that for 50 years we shall need from 500,000 to 1,500,000 tons of beet sugar annually. (649.)

Mr. SAYLOR says the demand for sugar increases at a very rapid rate. He thinks the annual increase for the last 30 years, according to statistics compiled by Dr. Wiley, has been 12 per cent. We can consume all the sugar we can produce and all we are likely to import from our island possessions for a long time. (589.)

Mr. ROGERS testifies that Binghamton, a town of from 45,000 to 50,000 inhabitants, expends \$500,000 a year for sugar. The Binghamton Beet Sugar Company has made something over \$100,000 worth a year; 3 such factories would not be able to supply Binghamton alone. (555.)

3. Imports.—Dr. WILEY says the imports of foreign beet sugar for the year 1898 amounted to 800,000 tons, while the production in the United States was about 50,000 or 60,000 tons. The import duty amounts to about 1.8 cents a pound. The imports of sugar from Cuba were formerly 1,000,000 tons; after the rebellion broke out, up to the time of the Spanish war, they fell to less than 200,000 tons. (653.)

Mr. SAYLOR says the Hawaiian Islands have been sending to this country about 250,000 tons of sugar annually, of which about 50,000 tons have been going around the Horn to the Eastern coast, the rest being absorbed by the Pacific coast and Missouri Valley trade; in 1899 the shipment was 282,000 tons. He estimates the maximum production of the Hawaiian Islands at about 450,000 tons annually; but this increase will involve a much higher cost, due to the necessity of growing sugar on higher lands, requiring a greater elevation of water for irrigation, and to increased wages. Porto Rico has been producing about 60,000 tons (and is probably capable of doubling that amount) and sending us about 5 per cent of our present consumption. Cuba is capable of a large output. (587, 588.)

Professor KEDZIE testifies that the supply of sugar from the West Indies and from the Philippines was cut off during the war, and that nearly all produced in the Sandwich Islands is used up on the Pacific coast, while that produced in Louisiana is no more than sufficient to supply that and the surrounding States. The great bulk of sugar consumed in this country of late has therefore come from Europe, and is produced from the sugar beet. (544.)

A director of the Michigan Sugar Company told Mr. Kedzie that his factory would produce 6,000,000 pounds a year, and that 7,500,000 pounds were required for the needs of the counties of Bay and Saginaw. The use of sugar, Professor Kedzie says, is constantly increasing. (543.)

Mr. SNOW testifies that before the reciprocity treaty of 1876 Hawaii produced about 20,000,000 to 30,000,000 pounds of sugar a year, and it was insisted that she had reached the limit of her production, but from that time on the sugar production of Hawaii increased by leaps and bounds, until the United States alone has imported 500,000,000 pounds in a year. Mr. Snow thinks this has undoubtedly been a detriment to the sugar industry of the United States. If the American sugar growers had been given the full benefit of tariff discrimination, they would have rapidly grown to a point where they could furnish a much larger proportion of the sugar. (241.)

The Philippine Islands export nearly 600,000,000 pounds of sugar in some years, of which the United States has never taken a very large share. If the duty were suddenly taken off, Mr. Snow deems it reasonable to suppose that practically all the sugar grown in the Philippines would come to the United States, and the production would be stimulated as it was in Hawaii. If this sugar were admitted duty free to the United States, the greatest sugar market in the world, the amount grown under the present shiftless methods would be sufficient to supply all the people living west of the Missouri River. If the production of the Philippines increased only 10 times, as that of Hawaii increased 24 or 25 times after the limit was supposed to have been reached, the Philippines could send us enough sugar to supply our whole demand. (241, 242.)

4. Tariff on sugar.—Dr. STUBBS says there has been a tariff on sugar ever since the introduction of cane into Louisiana in 1794, before Louisiana was admitted to the Union. During the Monroe Administration, 1812–1815, the duty was 5 cents a pound, and the only time sugar has been on the free list was during the bounty period. During the first year of the war the tariff was lowered to one-half a cent, the lowest it has ever been. (773, 774.)

Dr. WILEY says we have a countervailing duty on beet sugar; that is, the duty is increased on imports from countries giving an export bounty (e. g., Germany) by the amount of the bounty. (653.)

Professor KEDZIE, of the Michigan Agricultural College, thinks the sugar tariff should be continued. If it were removed, while Europe still offers export bounties, we should have cheap sugar, but no large production of sugar. It would be disastrous to cut the price of sugar down below the cost of production here. Ultimately, however, with the industry thoroughly established and with harmonious action between the farmers and factories, we should be entirely independent of the tariff. (543.)

Mr. SAYLOR predicts that the sugar industry will develop very rapidly in this country if free sugar is not admitted from our tropical islands until it has had a proper chance to get started. Mr. Saylor favors the tariff, if constitutional, because the cost of production is such that the islands can pay a fair tariff and still afford to make sugar. Moreover, the American Sugar Refining Company and the combinations which control the sale of sugar have contracts with the planters of Hawaii to refine their sugar and put it on the market, sharing in the profits at a stipulated rate. Mr. Saylor understands that the same thing is true with reference to Porto Rico; hence the only interests benefited by free sugar would be the producer and the company mentioned, and the planter in Porto Rico is, as a rule, a foreigner to both Porto Rico and the United States. (589.)

Dr. WILEY has never had any fear that the American sugar industry would be

COLXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

ruined by free sugar as a result of the Spanish war. He declares that the admission free of duty of every pound of sugar made in Porto Rico, Cuba, and the Philippines would not affect the progress of the sugar-beet industry in this country. There would still be a deficit to be supplied. We should still have to import sugar, and the duties on sugar imported from other places would probably remain the same as now and would tend to fix the price. It is not an unmixed evil to have a low price on an agricultural crop, because (1) it increases consumption, which tends to restore prices, and (2) it teaches economy in manufacture. If Louisiana people had been told a few years ago that they would have to sell their sugar at 2½ cents they would have held up their hands in horror, but they are doing it and making money. They had to change their agriculture and manufacture, and it has been to their benefit; they are in a better position than when they got twice the price for their product. (654.)

5. *Cost of producing sugar at home and abroad.*—Dr. WILEY estimates that sugar can be manufactured in Germany for 2½ to 2¾ cents a pound, exclusive of the tax, and in this country, under the best possible conditions, for perhaps 3 cents a pound. The actual cost in this country has probably been greater than that, because many unfavorable conditions have obtained, the business being new. (655.)

Dr. Wiley believes, however, that American machinery is so much more efficient than European, and fuel is so much cheaper and more economically used in this country, that we can make beet sugar almost, if not quite, as cheaply as it is made in Europe to-day, although we pay far more for beets and for labor. (640.)

Mr. SAYLOR says capitalists hesitate about investments until they know what policy is to obtain with reference to our new possessions, where it is understood that sugar can be produced very cheaply. Porto Rico can produce raw sugar and send it to this country for about 2 cents a pound; the tariff is \$1.68 per hundredweight. The cost of refining is about 65 per cent on the west coast and 55 on the Atlantic, making the cost of raising sugar in Porto Rico and placing it on the market here, refined, something over 2½ cents. In Cuba the cost is probably very nearly the same. In Hawaii there are factories that can produce sugar much more cheaply, but the cost of production and transportation to this country averages about \$40 a ton. In this country the cost of beet sugar ranges from 3 to perhaps 3½ cents a pound. Very little is known about what it can be produced for when the farm laborers and factory experts are all thoroughly trained. (587.)

Mr. Saylor says the only thing that gives Porto Rico, Cuba, the Hawaiian Islands, and the Philippines their great advantage in the production of sugar is the low cost of labor. In Porto Rico unskilled labor is 30 cents a day, without board, and skilled laborers, such as brick masons, carpenters, etc., get 60 cents a day. In Hawaii sugar has been manufactured largely by contract laborers, chiefly Japanese, at \$12.50 to \$15 a month, without board, the employer furnishing living quarters, medical attendance, etc. Similar wages were paid the Japanese and Chinese in California 20 or 25 years ago, but under the operation of Chinese exclusion and other influences they now receive about \$30 a month. There is now, however, a very noticeable tendency toward increased wages in Hawaii, and one of the great problems is where to get labor; Chinese immigration has been stopped. Probably wages will increase to about what is paid on the Pacific Coast, in which case it will cost as much to produce sugar in Hawaii and place it on our markets as it now does to produce beet sugar in this country. (585.)

Mr. Saylor adds that the tendency toward increasing wages applies also to Porto Rico and Cuba, where strikes for the 8-hour day and stipulated wages have been stimulated by emissaries of organized labor from the United States. (588.)

Mr. Saylor thinks that the cost of production will be reduced every year in the United States, while it will be increasing in Hawaii, Porto Rico, and Cuba. He considers the sugar industry a perfectly safe business to engage in. (588.)

6. *Price of sugar.*—Mr. WEDDERBURN understands that the sugar combination is all in the hands of one party, and that prices are raised and lowered at will. A few years ago sugar retailed at 5 cents, then went up to 6 and 6½, and in June, 1900, was selling for 5½ and 6 cents, according to the quantity purchased. (624, 625.)

Dr. STUBBS testifies that the price of sugar ("off whites" and "yellow clarified") has fallen in 16 years from 10 cents to 4 and 4½ cents a pound. (771.)

7. *Raw and refined sugar.*—Dr. WILEY says all the beet-sugar factories in this country, with one or two exceptions, make refined sugar and are totally independent of the sugar trust. There are one or two factories controlled by Mr. Spreckels that make raw sugar and send it to his refinery in San Francisco. (655.)

Professor KÄPPEL testifies that the Michigan factories produce sugar ready for the table, hence it does not have to pass through the hands of the sugar trust. He considers deliverance from that monopoly one of the best things to be secured from the enterprise. (543, 544.)

Mr. ROGERS testifies that the Binghamton Beet Sugar Company made granulated sugar the first year, but in 1899, owing to the sugar war, the difference between the price of yellow sugar and granulated sugar was less than one-half a cent, and the entire product of the factory was sold to the American Sugar Refining Company. If the difference were over half a cent, it would pay the factory to do the refining. (553.)

Mr. Rogers adds that the difference in cost between the granulated sugar and raw sugar is very slight, and it pays to equip a sugar factory for refining. The Binghamton Beet Sugar Company is not in the hands of any trust, because it is equipped to refine its own sugar. (559.)

Dr. STUBBS says the Louisiana sugarhouses have been forced to refine sugar because of the lack of competition in the markets. The American Sugar Refinery is the only buyer; hence few sugarhouses are unprepared to refine sugar when the prices for unrefined sugar are unsatisfactory. Dr. Stubbs thinks it is probably not best for the sugarhouses to refine sugar ordinarily, but says it is decidedly more profitable to refine it than to take whatever they can get from one purchaser. Whenever the trust will pay a fair price for 96 centrifugals, it is easier and more profitable for the sugarhouses to sell them, but whenever the price falls below such a point as will leave a profit they refine the sugar and put the refined sugar on the market. The so-called trust has no contract for the sale of the output of Louisiana, as is the case in the Hawaiian Islands, where several planters contract to make 96 centrifugals at a given price during the season. (771, 772.)

Dr. Stubbs explains that the process of granulating sugar consists simply in running the "off whites" through a revolving drum, where it is steam dried, preventing the cohering of the particles, or caking. A dozen or more sugarhouses in Louisiana granulate the sugar, but, as the Louisiana crop is consumed in a few months, it is not found profitable to granulate, because the "off-white" sugar will sell readily and will keep a few months without getting lumpy. Yellow clarified sugar is a refined sugar, very similar to "coffee A." It has a light-golden tint, which is given it artificially in the sugarhouse, and it meets all the requirements of ordinary family consumption. (771.)

8. Sugar from different sources compared.—*Cane and beet sugar.*—Dr. WILEY says beet sugar is not so well adapted to preserving as cane sugar. He predicts that the great use for cane sugar in the future will be for preserving, while beet sugar will be largely employed for ordinary table use. Beet sugar must be absolutely pure before it can be used, while cane sugar, to Dr. Wiley's taste, is a good deal better in its raw state; he knows of no sugar so good as the old-fashioned yellow Louisiana sugar, while unrefined beet sugar is so bitter it could not be eaten. There is no chemical difference between cane and beet sugar, but beet sugar, after being put away in a bottle for a week, gives an unpleasant odor, while cane sugar has a delightful aromatic odor. A beet-sugar factory smells like a soap factory, because the sugar contains a large amount of potash and some fat; while a cane-sugar factory has an aroma like a garden of roses. It is impossible to distinguish between the two kinds of sugar, however, in sweetened coffee and cake. (650.)

Professor KEDZIE attributes to the sugar trust the suspicion that beet sugar is not good for preserving, which he considers groundless. (544.)

Sorghum.—Dr. STUBBS says sugar is never made from Louisiana sorghum. It has been attempted, but found impossible. (775.)

9. Future of sugar production in America.—Dr. WILEY says the United States has a marvelous climate, with great possibilities of development, and, from an industrial point of view, the development of the sugar industry is worthy of consideration. (654.)

Mr. SNOW says we have every facility for sugar production in this country, but if the industry is not favored its development will be very slow. We have been 200 years in building up the iron industry. With anything like the same fostering care the sugar industry could be built up in a much shorter time. Eventually the United States will make its own sugar, and the sooner this comes about the better for all concerned. In the end, beet sugar will more than hold its own against cane sugar. In European countries, where the beet-sugar industry has been built up by the fostering care of government, beet sugar has entirely crowded out cane sugar. Mr. Snow objects to the admission of foreign sugar duty free. (241, 242.)

Mr. BRIGHAM, Assistant Secretary of Agriculture, says that it would be possible for this country to supply all the sugar it needs by means of beets. The pulp left after the sugar has been made can be profitably fed to cattle and the sugar would be largely pure profit. Nevertheless, if sugar can be raised in our new possessions for 2 or 2½ cents per pound, it might not be profitable to grow beets for sugar. (22.)

Mr. SAYLOR says we are only on the threshold of the introduction of this industry,

COLXXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

and mentions the possibility that we may some time be able to export sugar. (586.)

Mr. ROGERS has estimated that it would take over a million acres to produce the sugar consumed in the United States. Devoting this area to sugar beets would take it out of competition with other products, leave at home the money now spent abroad for sugar, and give employment to the unemployed. (561.)

XI. THE NATURAL ENEMIES OF AGRICULTURE.

A. Insect pests.—1. **The multiplication of injurious insects.**—Dr. HOWARD, Chief Entomologist of the United States Department of Agriculture, says that injurious insects were noticed as soon as man began to grow crops. The prophet Joel, whom Dr. Howard characterizes as an agricultural pessimist, mentioned several insects, including the grasshopper and the palmer worm. As agriculture has become more extensive, insects have found conditions more favorable for rapid multiplication. The cultivation of crops in enormous fields is particularly favorable to the increase of insects. In Europe, where the holdings are smaller and culture more intensive, less trouble is experienced than in this country. In the older agriculture of the South the caterpillar and bollworm were extremely injurious in cotton fields of from 500 to 1,000 acres, and the planters could not spray with ease. Now, with much smaller fields and more diversified agriculture, the conditions for the multiplication of insects are not nearly so good.

Dr. Howard says there is a certain balance in nature which has always been preserved, and in the state of nature each species seems to take care of itself pretty well; but man, by his extensive cropping, has disturbed the balance of nature, and the enormous multiplication of injurious insects seems to be an effort of nature to restore the original balance. (759.)

Professor BAILEY, of Cornell University, says that the insects and diseases which the farmer has to fight are more numerous and more serious than formerly, because of the introduction of new pests through commerce, and because of the greater variety of crops, the greater extent of crops of one kind, and the fact that the natural breeding places in the woods and fields are being eliminated. On the other hand, the farmer has more resources for the conflict than he had a generation ago. Much of the work of the experiment stations has been directed toward overcoming natural difficulties. In most cases the farmer has a recourse for the destruction of pests. Indeed, Mr. Bailey asserts, in another connection, that diseases and insects are under better control than they were 100 years ago. (1006, 1013.)

2. **Economic importance of insect pests.**—Dr. HOWARD estimates the annual loss to crops from the ravages of insects at about \$300,000,000, and says that live stock also suffers severely from insects. The farming class does not lose the amount stated, because of the enhanced price of the remainder of the crop when there is a widespread insect pest, but that increase in price means an economic loss to the country at large. Dr. Howard quotes Dr. James Fletcher, the Dominion entomologist of Canada, as saying that the United States leads the world in economic entomology, and that the damage to agricultural products by insects would probably be twice as great as it is were it not for the labors of economic entomologists. The General Government spends \$30,000 a year in supporting the Division of Entomology in the Department of Agriculture, and 30 of the 45 States have State entomologists who are investigating insects and publishing bulletins. At the foundation of the Department of Agriculture not a single reliable remedy was known for any injurious insect. At present there is a fairly good remedy for every insect of economic importance.

Dr. Howard says agriculture sustains the greatest loss from the codling moth or apple grub, the Hessian fly, and the chinch bug. He estimates the annual loss from these insects at \$60,000,000. (753, 754.)

3. **Insects injurious to grain.**—*Hessian fly.*—Dr. HOWARD says the Hessian fly is thought to have been brought to this country in the straw bedding of the Hessian soldiers in the Revolutionary War. This explanation has been disputed, however, and the matter can not be decided at this late date. (756.)

Dr. Howard says that an early strip of wheat is sometimes planted as a trap crop to allow the Hessian flies to concentrate, and the bulk of the wheat is planted later. Dr. Howard thinks this trap strip the best remedy yet found for the Hessian fly. Several of the State entomologists are working on that line, stimulated by the recent losses from the Hessian fly. One of the experts in the Division of Entomology is also devoting his entire time to the Hessian fly, and expects to publish a bulletin giving the results of his study. No extermination of the Hessian fly is to be expected, but a study must be made of the weather conditions and the probabilities of early or late falls in each locality. In bad years there must be some alteration of the method of

cropping. The study of crop conditions and the possibility of variation in the method of cropping is a very important point in economic entomology. (758.)

4. Wheat weevils.—Dr. HOWARD says that all the insects that are injurious to stored grain are cosmopolitan, because grain goes all over the world. There are several species of grain weevils. The one known as the fly weevil in this country is not strictly a weevil; it is a moth which lays its eggs in the grain. Where grain is stored in bulk a very satisfactory remedy is the evaporation of bisulphide of carbon on top of the grain. The vapor is heavier than air, and sinks down to the bottom of the grain and destroys the insects. Hydrocyanic acid is now being used against a new grain moth, known as the Mediterranean flour moth, which is becoming prevalent in this country. (758.)

Chinch bug.—Dr. HOWARD says the chinch bug is a difficult insect to get rid of. Almost the only feasible remedy is to attack it when it migrates from the wheat field to the neighboring corn fields, about the 1st of July. Much interesting experimental work has been done in Kansas with diseases of the chinch bug. Fungous diseases were propagated in the laboratory, and, under certain conditions, when the laboratory cultures were put out in the fields the disease was communicated to the bugs and they died in great numbers. This had to be done in very damp weather, however. The Division of Entomology has published a bulletin on the chinch bug by the Ohio entomologist, Professor Webster. (758.)

Grasshopper.—Dr. HOWARD says the migratory grasshopper bred in arid places in the foothills of the Rocky Mountains, and migrated to the fertile portions of Kansas and Colorado. They could live only one generation in the lower country. They could breed successfully in such enormous quantities only in their permanent breeding grounds, and the conditions brought about by the settling of the arid regions made that district unfavorable for their unrestricted multiplication. To this fact Dr. Howard attributes the nonrecurrence of the Rocky Mountain locust since 1876. He says the damage done nowadays by grasshoppers in the West is by the local non-migratory species. Once in a while a swarm of migratory grasshoppers will come down from the Assiniboine country and settle in North Dakota or Minnesota, but it is promptly stamped out. About 7 or 8 years ago a large swarm settled in Ottertail County, Minn. The Governor of the State authorized the purchase of several carloads of petroleum and certain destructive apparatus, and the State authorities, with the aid of the county officials, quickly wiped the pest out. When the young are hopping around a large sledge covered with kerosene is dragged over the ground and the grasshoppers light on the kerosene and are killed. Another remedy is late fall plowing, which breaks up the eggs and throws them out where the birds can reach them. There are migratory grasshoppers in South America and South Africa, where they also go down from the arid breeding ground to the cultivated land, and the same methods of extermination are used against them that are used in this country. (759.)

Dr. Howard says experiments are being made with a fungous disease brought from South Africa, which is used there against migratory grasshoppers. In localities in Colorado and in Mississippi it has been found that the disease has been readily communicated to healthy grasshoppers, and they died in great numbers. (758.)

5. Insects injurious to cotton.—Dr. HOWARD says the cotton-boll weevil is alarming Texas cotton growers very much. It has spread until it is now damaging some of the best cotton-growing regions in the State. A small sum has been appropriated for the investigation of this insect by the Division of Entomology, and the State of Texas has appointed a State entomologist to investigate it. It is a Mexican insect, but is gradually spreading northward, being perpetuated by the voluntary stalks of cotton which grow through the winter where there are no heavy frosts, and are cultivated because the Galveston board of trade offers a large sum of money for the first bale of cotton. Recent developments seem to show that it migrates north of the frost line, and perhaps it manages to survive the winter in small numbers, so that it may become much more serious than was anticipated; but it is still uncertain whether it will spread north of the line of heavy frosts. (757.)

Dr. Howard says the cotton-boll worm is a very serious evil in some parts of the South, but the planters get rid of it by diversified crops, and by using corn and cow peas as trap crops. The cotton planter now has a very good remedy for the cotton caterpillar, or army worm, which feeds on the leaves of the cotton plant; namely, an application of paris green. (757.)

Mr. HAMMOND, a cotton planter of South Carolina, says that the use of paris green, introduced through the Agricultural Department, has been very effective against insects injurious to cotton on the sea islands and the Mississippi bottoms. In the uplands there is little trouble from insects. The boll weevil has been seriously destructive in Texas, but the people seem to have been quite successful in restricting it. (833.)

6. *Insects injurious to tobacco.*—Dr. HOWARD says tobacco is attacked by the big horn worm, a very large green caterpillar, and also by a little beetle which eats holes in the leaves. The boll worm of cotton also attacks tobacco, and a new enemy has recently been discovered in the split worm, an extremely small caterpillar, which mines between the upper and lower surfaces of the leaf. Planters get rid of all the leaf-feeding caterpillars now by spraying with paris green, and experiments have shown that the paris green does not stay on the leaf. The idea is now being adopted that it is desirable to allow solanaceous weeds to grow, belonging to the same family with the tobacco plant. If they are allowed to grow before the tobacco comes up, all the tobacco insects concentrate on the weeds and are easily destroyed. This is known as using weeds as a trap crop. (757.)

Dr. Howard says that hydrocyanic gas is used against the cigarette weevil, which does great damage to tobacco. In the fall of 1900, in a large tobacco warehouse in Baltimore, it was found that hundreds of cases of tobacco were affected by this weevil. The tops of the cases were removed and the building was fumigated with this gas under police protection, because the gas is extremely poisonous. The fumigation killed the rats and mice which infested the building, as well as the weevils. (758.)

7. *Insects injurious to fruit.*—*San Jose scale.*—Dr. HOWARD says that insects have a certain range, governed largely by temperature, elevation, etc., and that some localities are protected to some extent from insect pests by climate. The San Jose scale, for example, which has been the basis for all State legislation on insects for the past 10 years, will not flourish where there is less than a certain amount of summer heat. This insect, which is one of the worst enemies to orchards, is at its worst in Maryland and Virginia, but is not so numerous in central New York and does not flourish in Michigan. It is present, however, in most of the fruit-growing States. It is found in Massachusetts, Connecticut, Rhode Island, and all the eastern and central States, and also in California, Washington, Oregon, and Idaho, but is not found in the group of States running from Iowa and Kansas west to California. The pest continues to spread, because, while 21 States have passed rigid inspection laws providing that no nursery stock enter the State without inspection, the States which have not passed such laws have become dumping grounds for infested nursery stock. (754.)

Dr. Howard says the San Jose scale was first discovered in this country near San Jose, Cal., and is thought to have come from Japan. It spread all over California, and was considered the most destructive scale in existence. It spreads almost entirely on nursery stock. About 1889 some Japanese plum stock was imported into New Jersey, and the scale was carried East on that stock, but was not recognized or called to the attention of entomologists in the East until 1893, by which time it had been distributed all over the Eastern States. When this was discovered the fact was widely published, and the States began to pass inspection laws preventing the entrance of nursery stock without inspection. In some States a certificate is required to the effect that the stock has been exposed to the fumes of hydrocyanic acid gas. In California a wash of lime, sulphur, and salt works well in dry weather. In the East a very strong solution of whale-oil soap and water is used; where that is not efficacious the use of crude petroleum on sunny days is now advocated. (755.)

Mr. CLOHAN testifies that it was discovered in 1895 or 1896 that the San Jose scale had been sent into Berkeley County, W. Va., from New Jersey, and infested 3 of the fruit farms. One of the infested orchards was in the hands of a progressive farmer, who has been constantly fighting the pest ever since, and has kept it in check, with no danger of spreading from his orchard, though he has not completely eradicated it. Another man neglected it, and the orchards all around him became infested. Apples, plums, and currant bushes were destroyed by the scale. If there had been a law giving some one authority to order the destruction of the trees, the pest could have been eradicated at very slight cost; now it exists in about 20 localities in the county. With the aid of the experiment station the farmers have held a meeting and subscribed funds to buy materials for treating these orchards. All this could have been prevented if there had been a law to prevent the sale of nursery stock unless it had been fumigated. The scale can be destroyed by fumigation in air-tight fumigation houses with hydrocyanic acid. The most effectual way to eradicate it where it obtains a hold in the orchard has been found to be by thorough spraying with crude petroleum, but if one spot on a tree is left untouched, and there is a scale there, it all has to be gone over again the next season. Some of the farmers in Berkeley County have used as much as 20 barrels of petroleum. (801.)

Other scales.—Mr. NARTZGER says the San Jose scale affects the pears, peaches, plums, prunes, etc., of California. The citrus fruit growers of southern California are not annoyed by it, but the citrus fruits are affected by the cottony cushion scale, the red scale, and the black scale. The cottony cushion scale has almost been

destroyed by the Australian lady bug, which was imported and propagated in California. The only satisfactory protection against the red scale so far is fumigation. (952.)

Mr. Naftzger says the Department of Agriculture has rendered California fruit growers assistance toward the extermination of the scales, but the chief work has been done by State horticultural commissions. Men have been sent abroad to study the pest destroyers of almost all fruit-growing countries. California has a very effective State law for subduing pests. (953.)

Codling moth.—Dr. HOWARD says the greatest apple-growing regions suffer the greatest loss from the codling moth. Certain sections, such as Michigan, western New York, and parts of Virginia, which formerly suffered great loss, have reduced the loss by the general introduction of remedies—first, the banding of trees and then spraying. (754.)

Mexican orange maggot.—Dr. HOWARD says he has on two occasions sent 2 men all over Mexico to investigate the Mexican orange maggot, and they found it in oranges in all parts of Mexico except in the State of Sonora, west of the Sierra Madre Mountains. When so many orange trees were killed in Florida in 1896 maggots were found in the Mexican oranges on the hotel tables. California fruit interests are greatly in fear of the introduction of this maggot, and want the Federal quarantine bill passed so that a quarantine can be established against Mexican oranges. The Mexicans say that the danger is overrated, and that this is simply an effort of the Californians to avoid the competition of Mexican oranges. Dr. Howard considers the matter very important, and believes that the American fruit grower should be protected. He thinks that the maggot will thrive wherever oranges grow. (756, 757.)

8. *Gipsy moth.*—Mr. STOCKWELL says the gipsy moth was brought from a foreign country by a scientist in Medford to improve on the silk worm. Professor Shaler, of Harvard, told him the danger, and an attempt was made to destroy them, but some escaped, and a few years later the people of Medford were at the statehouse saying that their houses and walks were covered with caterpillars that rendered life unbearable. The caterpillars multiply in large numbers and eat every green thing. A commission was appointed, but did not work satisfactorily, and the work of suppression was thrown upon the Board of Agriculture, which has spent \$1,100,000 in the work. In 1900, however, no appropriation was made for the purpose. The pest was under control, and in a few years would have been entirely wiped out. An investigating committee found that there was not a single large colony extant. (902, 903.)

Mr. Stockwell predicts that the State of Massachusetts will spend four times more money in suppressing the gipsy moth in the next 15 years than it would have cost to exterminate it, and at the end of that time the cost to individuals, State, and nation will have only begun. Though every reputable entomologist in the country urged forward the work, the leaders in State legislation believed it a fad. (903.)

Mr. Stockwell says many birds and some insects prey upon the gipsy moth, but not to any great extent. (903.)

Dr. HOWARD says the State of Massachusetts for some time appropriated \$150,000 to \$200,000 annually for the work of the gipsy moth committee, but in 1900 the legislature refused to make any more appropriations, and although the insect had been reduced to almost harmless numbers it is now beginning to spread again. It has not yet gone far outside of the old limits around Boston, but is very close to the New Hampshire line. Several years ago Senator Lodge introduced into the United States Senate an amendment to the agricultural appropriation bill appropriating \$40,000 to assist Massachusetts in the work of exterminating the gipsy moth, but the House did not concur in the amendment. Dr. Howard thinks that as the insect does not spread very rapidly it would be well to wait a year or two so as to judge of the rapidity of its spread before the Federal Government takes the matter up. (755.)

Dr. Howard explains that the gipsy moth spreads by the traveling of the caterpillar and by its being carried, e. g. by wagons, railroad cars, etc. Dr. Howard fully expects that if the State of Massachusetts does not resume the work of extermination the gipsy moth will in a few years be found in the surrounding States. (764.)

Mr. STOCKWELL predicts that when the gipsy moth covers the country it will be the greatest pest ever brought to America; it does far more damage here than in the Old World. Now that Massachusetts has given up the work it must be made national. An effort in that direction has been made by Congressman Thayer, and a committee was sent to Washington some years ago. Though a particularly dangerous insect, the gipsy moth can be exterminated if attacked at once. The female moth never flies, but remains near the place where it emerges; it lays 600 eggs on an average, and then dies. The pest, therefore, does not spread rapidly. The extermination of the gipsy moth is a matter that ought to be continued by the National Government, for the benefit of the whole country. (902, 903.)

9. Brown-tail moth.—Mr. STOCKWELL testifies that the brown-tail moth infests a considerable area in the eastern part of Massachusetts and is doing a great deal of damage. A strong effort is being made by Cambridge and other cities and towns to get rid of it by destroying the nests. It began in a very small territory, but spread constantly, and as the female flies over the country, extermination soon became impossible. The nest can be destroyed in the early spring; after that spraying is the only remedy, and it is hardly effective. (903.)

10. Clover-seed midge.—Dr. HOWARD testifies that the clover-seed midge does great damage to the clover crop. This insect has two generations, and the adults of the first generation issue just about the time when it is usual to cut the first crop of clover, so that they are able to lay their eggs and destroy the seed crop when it comes up. By advancing the time of cutting for hay a week or two the insect is absolutely destroyed, and this is now the general custom in Ohio. (758.)

11. Hop-plant louse.—Dr. HOWARD says the hop-plant louse, which annihilated the hop industry of Wisconsin and occasionally destroys the crop in New York, was brought to this country on imported plants. (756.)

12. Defoliation of shade trees.—Dr. HOWARD says there are three or four species of caterpillars that defoliate shade trees in all parts of the country, besides the imported elm-leaf beetle. In the moth stage they are nearly all strong flyers, and hence banding the trees is of absolutely no use as a remedy; if the band has any effect it will simply prevent the caterpillars from coming down. The elm-leaf beetle larva, however, descends to the ground to transform, so that many of them are caught; but the best remedy against this beetle is to spray the trees with some arsenical mixture and pour hot water around the trees after the larva comes down. In general there is no good remedy for the caterpillars that defoliate shade trees except spraying with an arsenical mixture. Dr. Howard says it should be the duty of every park commissioner of every large city to have a motor spraying apparatus and to have the trees sprayed at the proper time of the year. This has been done by the city of New Haven to save the large elms there, and has also been done in Central Park, New York, and Prospect Park, Brooklyn. It is very inexpensive. Dr. Howard says that in Washington, D. C., the superintendent of gardens and grounds sometimes sprays the trees in the parks after the insects have about disappeared, but even if he sprayed at the proper time it would be of very little use, because the parking commission does not spray the street trees, which the superintendent of gardens and grounds has nothing to do with, and which in some cases are very near trees in reservations, so that the insects can fly across the intervening space. The same difficulty occurs in certain other cities. Dr. Howard says the trees in the parks and the trees along the streets ought to be under the control of the same man or board.

The silver maple is one of the trees which is most affected by insects, being the favorite food of two or three of the most prominent of the shade tree caterpillars. The Norway maple is much better in that respect, and the oaks are very free from insects. The box elder is one of the worst trees that could be planted. The gingko tree, of which there are a great many specimens in Washington and Brooklyn, is the best shade tree from the standpoint of freedom from attacks by insects.

With care and the expenditure of a little money it is possible to keep these insects in check and ultimately suppress them entirely. The caterpillars are apt to do rather less injury in dry seasons than in damp seasons, being held in check by little gauzy-winged parasitic insects which can not fly in damp weather.

Dr. Howard says that in Washington, D. C., and in almost every city he knows of, only an insignificant portion of the available appropriation for trees is expended in the care of trees after they are planted, and even that portion is not wisely expended. (759-761.)

13. Agencies for suppressing insect pests.—*Importance of birds.*—Dr. HOWARD testifies that birds are very important in keeping injurious insects in check, and the shooting of birds increases the chances for the multiplication of such insects. An extensive series of examinations of the stomach contents of birds by the Biological Survey shows what birds are injurious and what are beneficial in that respect. The English sparrow is an unmitigated pest, although it will eat insects when it can not get anything else. A bird is not necessarily beneficial because it eats insects, for it may have a predilection for beneficial insects. There are probably almost as many insects that are parasitic, or that prey on injurious insects, as there are injurious insects; but the injurious species seem to be the more prolific. (761.)

Importation of parasites.—Dr. HOWARD explains that nearly every injurious insect has a certain number of parasites, the encouragement of which, however, is a very complicated matter and generally impracticable. In the case of some of the imported insects good work has been done by importing their natural enemies from the country of origin. The so-called white scale of California, which threatened the extinc-

tion of the citrus fruit industry of that State, was originally brought from Australia, where it was not very abundant. The inference was that it was kept in check there by some parasitic insect. The insect was found and brought to California, where it bred so rapidly that within a single year the white scale was practically wiped out of existence. The insect has been sent to Portugal and to Egypt, where the same pest prevailed. There have also been imported from Australia some little beetles that prey on the black scale of the olive, and have proved very efficacious in killing off the scale in certain parts of California. Recently another parasite has been brought from South Africa for the same scale. Several years ago a parasite was imported for the common cabbage worm, and another was imported for the Hessian fly, but it has disappeared. (761.)

Spraying.—Dr. HOWARD testifies that spraying is a most important remedy for the codling moth, the plum curculio, and all scale insects. (754.)

14. *State laws against insect pests.*—*Inspection of nurseries, orchards, etc.*—Dr. HOWARD says that only 21 of the 45 States have inspection laws which enable them to do any organized work against insects. The State of California protects itself admirably. Oregon also protects itself. Maryland is very well protected, though the law is not as explicit as it should be, and some of the nurserymen of other States object to its stringency. The Illinois law seems to work very well. The New York law, at least up to the last session of the legislature, did not prevent the admission of infected nursery stock from other States. California, on the other hand, prevents the admission of such stock, but does not prevent sending it out. A man who exhibits an infected tray of apples in Los Angeles is arrested and fined, but he is not molested if he ships the apples to Chicago. (763, 764.)

Dr. Howard states that nearly all of the State laws provide for the inspection of orchards as well as nurseries, and for the treatment of such as are found to be infested. Others wisely provide for the establishment of county or district boards of commissioners upon the complaint of a certain number of citizens that certain premises are affected by dangerously injurious insects, thus placing the State in a position to deal with any emergency that may arise. (768.)

Mr. FLANDERS, Assistant Commissioner of Agriculture, New York, says the State law requires that nurseries be inspected, and that means be employed to eradicate any diseases that are found. When a company receives a consignment of nursery stock from another State it must notify the department of the source and the destination of it. (999.)

Mr. MILLER says that Ohio has for some years had laws in regard to diseases among plants, fruit trees, etc., and that in 1900 an important addition was made to the laws for the suppression of the San Jose scale and other pests. An appropriation of \$15,000 was made and the matter was placed in the hands of the board of control of the experiment station, which appointed an inspector for the nurseries and orchards of the State. (618.)

State entomologists.—Dr. HOWARD says that 30 States now employ official entomologists in connection with the experiment stations. New York, Illinois, and a number of other States have very efficient service. Most of these officers were young men just out of college when first appointed, as there was a sudden demand for a class of scientists that did not exist. They have had to collect libraries and apparatus and educate the farmers, and it is only recently that some few of them have reached the position where they are able to make original investigations. (762.)

Dr. Howard says very few States make specific appropriations for entomological work, but many of them give funds to the experiment stations in addition to those given by the General Government, and these funds are distributed among the different branches of the work by the director of the station or the board of control. In Illinois, New York, and Texas, however, there are State entomologists supported by State appropriations. Dr. Howard considers the matter of sufficient importance to be dealt with by the legislatures, and thinks the work could have been done more efficiently with more liberal appropriations. (764.)

Horticultural quarantine in California.—Dr. HOWARD testifies that California has an admirable State quarantine against insects from abroad. At San Francisco a quarantine officer boards every incoming vessel and examines it for any nursery stock or vegetables which might carry injurious insects. If any insects are found the stock is fumigated or destroyed. The law has been sustained by the highest court of California. That law protects California, but does not protect the rest of the country. When the inspector finds a box of plants consigned to another State he notifies the Chief Entomologist of the United States Department of Agriculture, who immediately notifies the proper State officers, and they cause an inspection on the arrival of the stock, if they have authority to do so. In certain States, as in Massachusetts, where there are large importers of ornamental plants from Japan, there is no authority to

COLXXX THE INDUSTRIAL COMMISSION:—AGRICULTURE.

require inspection, but the State Board of Agriculture notifies the importers, "and if they feel like it they cause the stock to be fumigated, but if they do not feel like it, they are not obliged to fumigate." (756.)

Dr. Howard criticises the California law for lacking the important provision of the New York law, which prevents the shipment of infested material from within the State to points outside; and also because it has no provision permitting the acceptance of inspection certificates from properly qualified officials of other States or countries. (766.)

Desirability of uniform State legislation.—Dr. HOWARD says that even when the Federal quarantine law comes into effect it will still be necessary to supplement it by State legislation. The national bill deals with only one aspect of the question, and it will still be necessary for most States to keep in operation a good crop-pest law. Of the State laws the California law has stood the test for the longest time, and it is desirable that all States should enact legislation of a similar character. The greatest reason for uniformity in State laws would be obviated by the passage of a national bill, but in the meantime uniformity in State legislation is highly desirable. (768.)

Dr. Howard says that in the 4 years which have elapsed since the National Convention for the suppression of insect pests and plant diseases by legislation was held in Washington, a number of new laws have come into existence, and much experience in their operation has been gained. He suggests that uniformity of State legislation could very properly be discussed by another national convention composed, like the first, of representatives of State horticultural and agricultural societies, of the National Association of Nurserymen, and of the appropriate Divisions of the Department of Agriculture, with, perhaps, representatives from the State attorney-generals' offices. The duties of this convention should be to unite upon the details of the needed uniform State law. (769.)

State and Federal work.—Dr. Howard says there are so many different kinds of climate in the United States that an insect may be of great importance in one location and comparatively of no importance in the rest of the country. He suggests that in these cases the State affected ought to do the work rather than the General Government, except where the insect may be reasonably expected to spread over a territory comprising a number of States. (764.)

15. Proposed national quarantine.—Dr. HOWARD says there is no national quarantine against insect pests, though a number of foreign governments have quarantines against the United States. A quarantine bill has been before Congress for 3 or 4 years in one form or another. Senator Perkins, of California, introduced in the United States Senate in January, 1901, a bill (S. 5615, Fifty-sixth Congress, second session) identical with that which was reported favorably at the preceding session by the House Committee on Agriculture. The bill provides that the Secretary of Agriculture shall have power to quarantine against any other country absolutely if he has reason to believe that injurious insects are likely to come in, and also gives him power to designate certain ports where nursery stock must be imported and where it will be subject to inspection if not accompanied by a certificate from some official of the government from which it is sent. The bill also regulates interstate traffic in nursery stock, etc., leaving to the States simply the extermination of insects within their own borders. Dr. Howard submits a copy of the bill and portions of the report thereon. (755, 756, 763, 765-768.)

Attitude of nurserymen and fruit growers.—Dr. HOWARD states that the Federal quarantine bill was opposed by the nurserymen at first, because some of them thought that as most of their stock arrives in the cold months it might be injured by being opened for inspection. Dr. Howard knows of no other good argument against it. The quarantine is being especially urged by Californians, who are greatly in fear of a Mexican orange maggot which has not yet been introduced in California. (756.)

Mr. NARTZGER testifies that the California fruit growers are in favor of the Federal quarantine bill. He understands that it failed because the Eastern nurserymen objected to requiring inspection at the point of shipment and again at the destination; but the California fruit growers would not consent to striking out that provision. The Pacific coast is much in need of a quarantine law, not so much as regards interstate business, but as a protection against importations from abroad, particularly from Mexico, where the orange orchards are infested by the orange worm or Morales maggot, of which Mr. Nartzger has seen as many as 15 in 1 orange. A quarantine is also desired for the deciduous fruits. (965.)

Memorial of the American Association of Nurserymen.—Dr. HOWARD quotes from a memorial prepared by a committee of the American Association of Nurserymen praying for the passage of the Federal quarantine bill, to the following effect: The chief danger to the nursery interests of the country arises from the passage of diverse laws by the different States, many of them very drastic and practically prohibitory, so

that an honest nurseryman is unable to send even clean nursery stocks into many of the States, while a dishonest or careless man may send infested stock to the States which have not yet protected themselves. These difficulties can be reached only by a law governing interstate commerce. Moreover, besides the actual damage done by the San Jose scale, the fact that a nursery has become infected by it has, in many cases, entirely destroyed the reputation and credit of the firm. The memorial declares that the varying requirements of the States and the lack of any law in certain States have produced a condition intolerable to nurserymen and of great danger to orchardists. Different forms of certificate are required for different States, and some States requiring no certificate are made the dumping ground for infested stock. New York prohibits the sending out of infested stock, but does not prohibit its entrance. The memorial urges the necessity for a uniform national law. (765.)

Report of the House Committee on Agriculture.—Dr. HOWARD quotes extracts from the favorable report of the Committee on Agriculture of the House of Representatives on the Federal quarantine bill. The committee reported that the bill had been indorsed by representatives of the entomologists and vegetable pathologists, as well as by nurserymen and fruit growers. The report goes on to say that at San Francisco 122 vessels had arrived during the year with trees, plants, and fruit from foreign countries, and that the quarantine officer had destroyed over 3,000 trees and plants infested with insects new to California, and thoroughly fumigated other stock with hydrocyanic acid gas. California, however, is the only one of the great ports which is thus protected, and there are many European, West Indian, and Mexican insect pests which are liable at any time to make their appearance in this country, where foreign insects thrive more than in their native homes. The California officers have jurisdiction only over shipments intended for California, so that the quarantine does not protect the rest of the country. The committee estimates that if a quarantine service such as that proposed had been in operation at all the principal ports of the United States during the past 30 years, its cost would have compared with the actual saving to the agricultural and horticultural interests of the country as 1 to 100, and that such a service in the future would result in an equal and probably greater relative benefit on account of the increased foreign trade. The committee calls special attention to the damage done by the San Jose scale, especially in Georgia, Maryland, North Carolina, and Ohio, and declares that the danger from this insect is greater in this country than in any other on account of the very extended interstate commerce conducted by nurserymen and orchardists. (765, 766.)

Need of national quarantine.—It seems to Dr. HOWARD very desirable that there should be a Federal quarantine against insect pests. There are now in this country perhaps 75 kinds of injurious insects of first-class importance, and more than half of these have been imported from abroad. They have come very largely through unrestricted commerce in plants, and are still coming in every year. The States which have no inspection laws are constantly in danger of the San Jose scale and other insects. Dr. Howard declares that either the bill must pass or the States must pass uniform laws. At present one form of certificate is required by one State and another by another, and it is necessary for a nurseryman to have before him condensations of 21 sets of laws and forms of inspection to consult when he ships stock. (766, 763.)

Mr. HALE says the entomologists have got up an unnecessary scare about the San Jose scale, which is no more dangerous than some other pests we have had in the country, and the different States have enacted various laws, which have been a very great hindrance to the nurserymen and a disadvantage to the small planter generally. In view of the necessity of some regulation, Mr. Hale approves the bill introduced in Congress putting the matter entirely in charge of the Secretary of Agriculture, requiring the inspection of stock coming from foreign countries and of nurseries in this country, and the issuing of certificates assuring admission to all the States. (400.)

B. Diseases of animals. (See also *Bureau of Animal Industry*, XVIII A 2, p. cccxlviii; *Exclusion of American cattle from European countries*, XV B 3, p. cccxlv.)—**1. Loss of animals from disease.**—Dr. SALMON, chief of the Bureau of Animal Industry in the United States Department of Agriculture, says that while American farmers have suffered from diseases of animals, especially hog cholera, sheep scab, and Texas fever, as compared with European stock raisers they have little idea of the devastation which animal plagues may cause. Pleuro-pneumonia was stamped out before it did much direct damage. Foot-and-mouth disease has been introduced several times, but each time was eradicated before it covered much territory. Rinderpest, which has at times almost exterminated the bovine population of other countries, has never reached our shores. Since the animal quarantines were placed under the Bureau of Animal Industry all these exotic contagious diseases have been excluded. Tuber-

culosis, however, which affects all warm-blooded animals and is the most fatal of human diseases, while it now affects but a small percentage of our animals, is undoubtedly becoming more common. Except in States where proper regulations are enforced, herds are frequently found containing 80 to 90 per cent of tuberculous animals, though the general average among dairy and breeding cattle is probably not more than 5 per cent, and among beef cattle still less. The inspectors of the Bureau of Animal Industry condemn more beef carcasses for tuberculosis than for any other cause, the number being 4,194 in the fiscal year 1899-1900; there were also 4,379 hog carcasses, and 1,061 parts of carcasses condemned for the same disease. In some European countries nearly or quite half the cattle are tuberculous. (748.)

Dr. Salmon thinks the loss from some diseases is as great as formerly. In other cases this is not true. He supposes the loss from hog cholera is as great as ever, the number of swine having increased, though the percentage has been lowered somewhat by following the hygienic regulations recommended by experiment stations and the Department of Agriculture. Hog cholera perhaps causes the greatest number of deaths of any disease attacking animals in this country. Glanders is probably just as prevalent as it was 10 years ago. Tuberculosis is more prevalent and constantly increasing. (753.)

Dr. Salmon says it is impossible to calculate accurately the loss from the death of animals from infectious diseases. The Division of Statistics of the Department of Agriculture sometimes states the loss of animals from disease, but it is impossible to distinguish between diseases. (749.)

Professor DAVENPORT says that a new country does not have the germs of animal or human diseases. There is more disease in this country now than when the country was new, with the exception of cholera. He thinks the thicker the human and animal population becomes, the more tuberculosis there will be. He does not consider it such a dangerously contagious disease as some do, however. (272.)

2. Tuberculosis in cattle a danger to human life.—Mr. SPEAR says that while the matter is still in dispute the evidence is convincing to him that it is possible for tuberculosis to be conveyed from animals to human beings. He does not think such conveyance is very common, but he has known of several cases in which herds of cattle were badly diseased, and in which some member of the family who had been a large user of milk was suffering from tuberculosis without any other known cause of contagion. (409.)

Mr. HAMILTON says that while doctors disagree about it the general impression among the best veterinarians is that tuberculosis is transferred from the milk of cows to human beings. (372.)

Mr. SNOW, statistician of the Orange Judd Farmer, says that there is some difference of opinion among scientists as to the exact stage which tuberculosis must have reached before it becomes a menace to those who use the milk or the meat. In the case of a dairy cow, unless the disease has affected the udder and the milk glands, the milk may not be affected. Mr. SNOW is entirely convinced that when the milk glands are affected the use of the milk is a serious danger to public health. There is less danger in the use of meat, because thorough cooking nearly insures safety.

Mr. SNOW says the most highly organized dairy cows seem most liable to be affected by tuberculosis, though all classes of cattle are attacked.

In the early stages there is very little sign of the disease. It can be detected only by the tuberculin test—injecting virus and watching for a rise of temperature. (238, 239.)

Mr. GEHRMANN says that the carcass of a thoroughly diseased animal may be so dressed and exhibited that only expert scrutiny will show the unwholesome character of the meat. A very strict supervision is necessary to prevent such practices. Diseased conditions may be overlooked. One carcass may be substituted for another, and decomposition may develop because of uncleanness in handling the meat. (635, 637.)

3. Pleuro-pneumonia.—Mr. STOCKWELL, of Massachusetts, says that when pleuro-pneumonia was brought here by cattle from Europe 40 years ago, the Massachusetts legislature made an appropriation at the very beginning and the Board of Agriculture killed every infected or exposed animal and stamped out the disease in 2 years, so that it did not spread beyond the borders of the State. (904.)

Mr. SNOW says that several years ago there was a good deal of pleuro-pneumonia in this country, the fear of which had begun to affect our export trade in meats. The Bureau of Animal Industry was organized at that time, and an appropriation was made for eradicating pleuro-pneumonia. The law authorized the condemning and killing of animals found to be affected with the disease. The result is that pleuro-pneumonia is almost completely eradicated. The matter was taken up by the National Government because it is almost impossible to get uniform and effective State legislation. (237, 238.)

4. Texas fever.—Mr. HAMMOND, a cotton planter of South Carolina, says that Texas fever has killed many cattle in his region. The stock business there has now fallen to nothing. Scarcely any animals are kept, except mules and horses. The Department of Agriculture has done a valuable work in restricting the Texas fever. (833.)

Dr. SALMON says that in several counties of Virginia the Texas-fever ticks have disappeared as the result of a law prohibiting cattle from running at large and requiring them to be fenced in on the premises where they are owned. (747.)

Dr. STUBBS says Louisiana suffers somewhat from the operations of the Texas-fever quarantine law. Only in 2 months of the year can cattle be shipped to the North. The effect of this is being counteracted, however, to some extent by the introduction of a better class of animals, which are inoculated and become acclimated. (784.)

5. Diseases of swine.—*Trichinae*.—Dr. SALMON says trichinae are found in American pork in larger proportion than in most other countries. This appears to be due to the practice of allowing hogs to eat dead animals, such as rats and mice, and particularly hogs which have died of cholera. The impression prevails in hog-raising districts that the feeding of meat lessens the losses from cholera, and so in cholera outbreaks it is quite common to encourage the swine to consume the carcasses of the animals which die, and if one is infected with trichinae that is sufficient to infect the whole herd. Two per cent or more of the hogs that come to our markets are infected, and in some large lots of hogs 25 or 30 per cent have been found with trichinae. (747.)

Swine plague.—Mr. GEORGE says swine plague prevails because the corn fed to swine is starchy, and lacks the nitrogen and phosphates necessary for muscle and bone development. Clover is a splendid ration for domestic animals, being highly nitrogenous. (223.)

6. State laws and their administration.—*Vermont*.—Mr. SPEAR, who had charge of the Vermont Cattle Commission for four years, believes that the Vermont law has been very effective in controlling contagious diseases among cattle. No animal for breeding purposes can be brought into the State without having been tested for tuberculosis. Tests are made upon the application of the owners of the cattle, and animals that are found to be tubercular are destroyed, the State paying half their value. Farmers who suspect that their cattle are infected are ready and eager to apply for inspection. They realize that a partial loss now will save a total loss later on. There does not seem to be much disposition to try to dispose of diseased cattle. Over 20 per cent of the cattle in Vermont have been tested. (409, 410.)

Massachusetts.—Mr. STOCKWELL says the Massachusetts Cattle Commission is holding contagious diseases of animals in check and preventing their influx into Massachusetts. The appropriation is not sufficient to wipe out tuberculosis. The commission is authorized to destroy infected cattle, a slight compensation being provided for, but does not go as far as formerly in cleaning out disease. (903, 904.)

New York (See also *Working of laws against tuberculosis*, p. CCLXXXIV.)—Mr. FLANDERS, Assistant Commissioner of Agriculture, New York, thinks that there is sometimes danger of prescribing the duties of State agricultural departments too specifically in the statutes. Thus his own department is authorized to suppress foul brood in bees; it is now embarrassed by the appearance of a kindred disease, black brood, which the statute does not authorize it to deal with. The New York Department of Agriculture is also authorized by law to treat tuberculosis and glanders among animals. Good results are obtained except in the case of tuberculosis, which has only just been placed under the control of the department. (999.)

Pennsylvania.—(See also *Working of laws against tuberculosis*, p. CCLXXXIV.)—Dr. SALMON, chief of the Bureau of Animal Industry, thinks that Pennsylvania probably has the best regulations for the inspection of cattle and prevention of disease. The State veterinarian, with the assistance of deputy inspectors, works under the State Department of Agriculture. The State has probably expended over \$30,000 annually of late in tuberculosis work. (749.)

Ohio.—Mr. MILLER, secretary of the Ohio State Board of Agriculture, says that the Ohio law for the prevention of the spread of diseases of animals is not very rigidly enforced. It is in the hands of a Live-stock Commission of 3 members, who serve without pay. The board has not proved efficient. Because this board has not been in position to cooperate with the United States Bureau of Animal Industry, the State has profited little by the provisions of the Federal law for the condemnation of diseased animals. (617, 618.)

Illinois.—Mr. WILSON says the law against the spread of disease among animals seems to be very carefully administered in Illinois, at least as to tuberculosis. Many cattle have been slaughtered. (255.)

North Dakota.—Mr. BUDGE says the laws of North Dakota for preventing the spread of diseases among domestic animals are executed by the State veterinarians. When stock is destroyed some compensation is made, but very little. (858.)

Kentucky.—Mr. NALL says the Kentucky law to prevent the spread of disease among animals is administered under the State Board of Health, which has a veterinary assistant. The law can not be enforced properly because the shipper from another State has certain rights under the Federal law that can not be properly regulated by a State law. Stockmen apply to the State Département of Agriculture for remedies for diseases, and Mr. Nall turns them over to the medical or veterinary department. He thinks possibly it would be better to have such laws enforced by the agricultural departments of the various States rather than the boards of health. In diseases of live stock, the live stock people know better what to do than the regular physicians. He adds, however, that the appropriation for his department would have to be increased, or the execution of the law would detract from other work. The appropriation for the bureau is \$13,000 a year, out of which are paid the salaries of the commissioner and his assistants and all printing expenses; there is not enough left to undertake to regulate diseases among live stock. It is quite an expensive thing to destroy a herd of cattle, just as a runty calf killed on a railroad sometimes becomes a very fine pedigreed animal; their apparent value increases very largely when they are taken for public purposes and destroyed. The Board of Health now has authority to destroy diseased stock, compensating the owner. (814.)

Louisiana.—Dr. STEUBBS says that in January, 1901, there was an epidemic among the animals in the parishes around Shreveport, and the veterinary surgeon spent nearly a week there destroying animals and giving instructions to the police juries of the parishes for disinfecting the stables, etc. The trouble was all due to a carload of animals brought from Idaho and Montana. (784.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, says that all cows brought into the State are quarantined at Pittsburg and tested for tuberculosis. The State board also inspects domestic cattle. Owners of herds are invited to ask for tests if they suspect that tuberculosis exists among their cattle. Before a test is made the owners must agree that any animals that are found diseased shall be slaughtered and that proper care shall be taken to prevent the spread of the disease. Slaughtered animals are appraised and paid for by the State—an ordinary cow at not more than \$25, and registered animals at not more than \$50. These regulations do not apply to beef cattle. In the beginning of the work, about 1896, 25 per cent of the cattle in inspected herds were tubercular. The proportion is now reduced to 11.6 per cent.

The number of cattle tested up to the time of Mr. Hamilton's testimony, June 9, 1900, was 33,147; 4,561, or 13.7 per cent, were tubercular; for these \$102,909 was paid, or an average of \$22.56 per head. The State board has a right to enter a man's premises and inspect his cattle without consent, but does not use the right. All tests are made by request of the owners. (372.)

Mr. Hamilton says that among the thousands of tuberculous cattle detected and slaughtered in Pennsylvania only one is known to have reached the butcher. That case came to light through the boasts of the guilty man. He bought the carcass for dog meat, and instead of using it for dogs sold it to the butcher. (373.)

Working of laws against tuberculosis.—Mr. NORRIS believes that great hardships arise from the law regarding tuberculosis in New York. He has been assured that there is hardly a single Jersey in the State but will respond to the tuberculin test when the animal is in just the right state. On the other hand there are diseased cattle whose owners get from the State more than they are worth. So while the enforcement of the law is sometimes injurious to cattle owners, it is at other times injurious to taxpayers. (332.)

Mr. SNOW, statistician of the Orange Judd Farmer, says that New York and Massachusetts have spent a great deal of money in trying to stamp out tuberculosis in cattle, and have succeeded to some extent, though not completely. In Illinois the State is just beginning to take the matter up. The disease is undoubtedly increasing there. (238.)

General criticism of State laws.—Mr. GEORGE says there is no uniformity in the matter of the State laws to prevent the spread of domestic diseases among domestic animals. One State may have a very severe law, and another no law at all. He thinks some of the State laws are rather arbitrary, and that lawmakers should be very conservative about condemning animals without due compensation on the theory of some veterinary surgeon that they have disease. Contagious diseases are not as injurious in this country, where cattle have free access to pure air, as in older countries. Pleuro-pneumonia, for instance, is generally confined to animals kept in stables. (226, 227.)

Professor DAVENPORT does not think it possible to be too strict in laws for preventing the spread of animal diseases. The health of animals must be protected both for the good of the live-stock interest at home and to prevent any objection to our goods abroad. He thinks there is sometimes a tendency to go to extremes in enforcing these laws, however. (272.)

7. Proposed State legislation.—In Dr. SALMON's opinion, what is most needed in the way of State work for the control of animal diseases is the thorough control and eradication of such diseases as glanders, tuberculosis, and rabies. There should also be State laws prohibiting the feeding of the carcasses of dead animals to swine, to prevent the spread of trichinæ. The destruction of the Texas-fever tick in the infected districts is also of great importance. The tick may be destroyed either by keeping cattle from a particular area for a year or two or by keeping the ticks picked off or destroyed by applications. Measures to insure the wholesomeness of the milk supply are also of great importance; and there should be more efficient measures to guard the public from being imposed upon by impure, adulterated, or renovated butter and filled cheese, the sale of which as high-grade goods defrauds the consumer and injures the dairy industry. There should also be a better local inspection of meats, and more efficient measures to secure the proper disposition of meat from diseased animals. (746, 747.)

Dr. Salmon doubts whether it is practicable to get enough money from fines for violations of milk and meat laws to pay the expenses of inspection. A man inspecting meats is morally certain of a great many violations for every case in which he can get evidence enough to convict. Where a fine is very heavy the tendency is usually to let the offender off; the law is more apt to be enforced where the fine is moderate. Dr. Salmon approves the plan of quadrupling the fine after the first conviction, as is done in some Eastern States. He thinks it more practicable to enforce a charge for all meat inspection rather than to depend upon fines to pay the expenses of inspection. (752.)

Mr. MAGIE, a dairyman and stock raiser of New Jersey, says that the dairymen of his State are sometimes troubled with tuberculosis in their cattle, and that it is very detrimental to them that there is no law to prohibit the shipment of cattle into New Jersey without being tested for tuberculosis. A great many cows are brought into the State for sale, and the dealers and their friends do not want any hindrance put upon the traffic. (101.)

Need of more efficient local meat inspection.—Dr. SALMON says that while the Federal inspection is applied to all meats slaughtered in the abattoirs where the inspection is established, the law permits the local sale of the condemned meat. The natural effect of the Federal inspection is to drive the diseased animals to abattoirs which slaughter for local consumption, and consequently much more diseased meat is put upon the market in cities where the Federal inspection is in operation than was the case before the inspection was commenced. Very few, if any, cities have a sufficient force of competent meat inspectors to protect their citizens from diseased and unwholesome products. (747.)

Dr. Salmon adds that meat inspection in the cities usually does not amount to very much, because there are not enough inspectors to control the local slaughterhouses. Almost every city has a large number of slaughterhouses in the suburbs in which diseased stock is slaughtered, and thorough inspection would require as many inspectors as there are slaughterhouses, which would mean 75 or 100 inspectors in a city like Philadelphia. The only practicable way to have inspection of animals slaughtered for local consumption is to have the killing concentrated. (750.)

Control of milk supplies.—Dr. SALMON says that in towns and cities the wholesomeness of the milk supply is usually in the hands of the health authorities, but they seldom have the money or the authority to inspect the stables and the cows from which the milk comes. As numerous diseases may be carried in milk, and other diseases and digestive derangements may result from contamination, there should be some system which would insure clean stables, healthy cattle, and a proper handling of the milk. The increase of tuberculosis among dairy cows and the danger of conveying the disease to the consumer, and especially to children, emphasizes the importance of looking after the milk supply. It appears to Dr. Salmon that this could be most effectively done by State boards applying uniform regulations to the dairies of whole States. Where it is necessary to eradicate a disease like tuberculosis, the cattle owner should be compensated for the animals destroyed. (747.)

Compensation for animals.—Dr. SALMON says there is a great difference of procedure among the States in the matter of compensation for destroyed animals, but the tendency and the precedent among lawyers are against compensation. In the veterinary profession the tendency is in favor of compensation, because it has been found in all cases that it was cheaper to give compensation and have the stock owners with the authorities than not to give compensation and have it to the interest of everyone to conceal contagious diseases. (749.)

Mr. SNOW believes that where tuberculosis is far advanced the danger to the community from the existence of the animals is so great that no property right in them should be considered to exist; but for the milder cases a payment proportioned to

CCLXXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

the value of the animal, taking into account the progress of the disease, ought to be made. (238.)

Difficulties of State control.—Dr. SALMON says there are two difficulties in the State regulation of animal diseases: (1) To get money enough, and (2) to enforce the law. The nearer the Government gets to the people the harder it is to enforce laws which bear upon the people of any section. The Bureau of Animal Industry, under the Federal law, can go into the States and do things easily which State authorities cannot do at all, because the people feel that the State authorities are more subject to them than the Federal authorities are. When city authorities adopt an ordinance requiring dogs to be muzzled, a large number of the citizens always object to the ordinance and say that it is unnecessary and cruel, and it can not be enforced. Even in Washington, although the Commissioners of the District of Columbia are not so much subject to the people as the officers of other cities, public clamor prevented the enforcement of regulations requiring dogs to be muzzled, and as a result, for more than a year there has not been a month without rabies, and about 30 or 40 people have been bitten and obliged to take the Pasteur treatment, at considerable expense. New York, which is one of the strongest cities, undertook to eradicate pleuro-pneumonia in 1879 and 1880, but stopped because the work was not popular; and when the Bureau of Animal Industry took up the work there was just as much pleuro-pneumonia in the State as ever. The same was true in New Jersey, where the State authorities undertook to stamp out the disease and failed. It is only in instances where the disease is not very widespread and where it can be eradicated without much hardship or inconvenience to the citizens that State authorities appear, to be able to work efficiently in such matters. (748, 749.)

Dr. Salmon knows of no State which has a sufficient inspection to prevent spread of glanders in horses, of which there is more or less probably in every city of the country. (750.)

8. *Proposed national legislation.*—Dr. SALMON believes that the Secretary of Agriculture should have authority to cause the cleaning and disinfection of stock cars and stock yards whenever necessary, to prevent the spread of hog cholera, sheep scab, glanders, and other diseases. The Department of Agriculture should also have specific authority to require the proper disposition of diseased meat. The Secretary of Agriculture should be authorized to make regulations prohibiting the shipment of uninspected meat from State to State or to foreign countries, in so far as he deems it necessary. Dr. Salmon suggests a more comprehensive penalty clause for shipping condemned meat than is now in force. He also considers it desirable that the Secretary of Agriculture should be authorized to inspect and certify pure, high-grade dairy products for export. Railroad companies in the hands of receivers should be made liable for violations of the law prohibiting shipment of diseased animals from State to State; the Supreme Court has held that the term "owner or manager" does not cover a receiver. (745, 746.)

Mr. NALL thinks there should be a Federal law to prevent the spread of diseases among animals. (814.)

Mr. CLOHAN, of West Virginia, advocates both State and national laws to prevent the spread of diseases among domestic animals. (601.)

Mr. BUDGE, of North Dakota, is not inclined to favor Federal legislation for the prevention of diseases among animals, but says it would be a good thing if the legislation could be made the same in all States. (858.)

Mr. STOCKWELL, secretary of the Massachusetts State Board of Agriculture, would recommend any legislation by which disease can be wiped out of the country. (904.)

Glanders.—Dr. STUBBS thinks the United States Government ought certainly to prohibit the importation of glanders from State to State as it does pleuro-pneumonia in cattle, for glanders is just as bad among horses and mules as pleuro-pneumonia is among cattle. There have been a dozen outbreaks of glanders in Louisiana in about 16 years, and the disease is always imported. (784.)

Tuberculosis.—Mr. SNOW believes that the Bureau of Animal Industry, which has done such splendid work in the eradication of pleuro-pneumonia, could do equally good work in stamping out tuberculosis. The experience of the States in the matter has not been entirely satisfactory. (238, 239.)

Sheep scab.—Mr. GREELEY, of South Dakota, says that in no country have local laws ever amounted to anything in driving out sheep scab, and cites the experience of Australia as an illustration. He declares that we cannot do anything with scab in our large flocks of sheep by State laws. Dr. Salmon has done a great deal of good, but he ought to be helped by some general law. (941.)

XII. BUSINESS RELATIONS OF THE FARMER.

A. How prices are fixed.—1. Demand and supply.—Mr. HYDE, Statistician of the Department of Agriculture, says 5,000,000 American farmers cultivate areas of from 3 acres to well up in the tens of thousands. Some products are consumed largely at home; one or more products, however, each farmer raises to sell. All that is raised in one place, whether for farm consumption or for local or distant markets, has some relation to what is raised elsewhere. It is finally the supply in relation to the demand which wholly or partly fixes the price and determines the profit or loss. The all-important question is how to secure the market, for, without a market, surplus production above farm consumption is a loss to the extent of its cost. (841, 842.)

2. Wheat prices in the markets of the world.—Dr. CROWELL says the price of wheat is fixed in Liverpool, the meeting point of the competing supplies. If the export prices rise, the domestic prices will rise, because Liverpool, New York, and all other places compete for the total crop. The market of largest consumption is the main factor in determining the price. (343, 344.)

Mr. BRIGHAM says the price of wheat is fixed almost altogether by the price in Liverpool, notwithstanding the fact that only 10 per cent of our American wheat is sold in foreign markets. If more than is needed to supply the wants of England is offered at Liverpool, the prices will tend to fall greatly. On the other hand, the European consumers must have their grain, and are frightened at any prospect of a shortage. If the farmers can know that a shortage is likely to occur and hold back their grain temporarily, they will make large profits. The witness does not consider it possible to form so thorough an organization of farmers as to control the market, but it may be possible to get them to withhold a part of their product when prices fall below the cost of production. It would pay them to throw away part in certain cases for the sake of a higher price for the remainder. It would be especially desirable, where there is an oversupply, to feed grain to cattle. The witness also thinks that America should not send wheat itself abroad, but only flour, keeping the bran and shorts and fertilizing material at home. (21.)

Mr. WEDDERBURN says the surplus fixes the price, and England, controlling the India surplus, tries to increase it, and pays for it in silver to beat down the price. For more than 20 years England has bought wheat at a rupee a bushel. The farmer in America must take the Liverpool price (less the cost of transportation to Liverpool), in competition with the cheap labor of India, Africa, and Russia. (627, 632.)

Mr. MORAN says that Liverpool being the chief market of the world for agricultural products, the farmers throughout the world will receive the ruling price at Liverpool, less freight, storage, commission, and other charges usually made in marketing farm products. The export trade sets the price upon the wheat sold at home. The Chicago, Minneapolis, and Duluth boards watch the cable news. Home consumption has nothing whatever to do with setting the price upon wheat. The surplus of wheat, though small, usually from 100,000,000 to 125,000,000 bushels, sets the price upon every bushel of wheat raised in the United States. If the surplus could be wiped out by procuring an additional market, we should not be at the mercy of the Liverpool market as now. (712, 714, 715.)

Mr. BUDGE says the markets of Chicago and Liverpool are very close together, but he thinks the price is fixed where the wheat is consumed. To a certain extent the surplus makes the price; if there were no surplus the price of wheat would be higher. (857.)

Mr. PRATT, of Aberdeen, S. Dak., says the price of wheat for that section is fixed at Minneapolis. He is inclined to think that Liverpool fixes the price of wheat in the United States to a large extent; when other producing countries throw their wheat into Liverpool we have to compete with them. If the Liverpool price advances, it affects Chicago and the Southern States, and they affect Minneapolis to a certain extent; but Minneapolis will be above Chicago, because of the local demand. (727.)

Mr. TURNBULL declares that the price of wheat to the California farmer is the Liverpool price, less the freight. (985.)

Mr. MILLER says plenty of economists claim that the value of grain is always fixed at Liverpool, and argue that an export bounty would increase the value of home products by the amount of the bounty. Mr. Miller believes that the conditions all over the world, including the weakness of human nature, makes the prices at Liverpool, and that the farmer does not always get the worst of it. (617.)

Mr. POWERS says the prices of our products are fixed very largely in the world market, but the markets of the world are dominated by the products of American farms. The price of wheat on the farm is the price in Liverpool, or any great mar-

ket, minus the price of sending it there; but during a series of years the price of wheat in the markets of the world is determined by the cost of production and transportation. The farmer who can produce large quantities of grain cheaper than the rest of the world does more to fix the price than any other individual. Foreign production and consumption unite with home production and consumption in fixing the price of any common product of the farm or shop. The price is highest where the people buy most and produce least; Liverpool for wheat, Asia and Africa for iron. The farmers of Minnesota, who raise millions of bushels and determine the price of wheat, are not suffering as much as the farmers of New England who are raising only a little. The Western farmers who are dominating the market are not suffering, but the men in the East who are seeking to produce farm products in competition with them are suffering. The price of wheat is determined by the small farmer of the West, who, by having a widely diversified system of farming, works 300 days in the year, and not by the farmer of Argentina or India, who works 60 days in the year. When a man who works only 60 days a year raises wheat and comes into competition with those who work 300 days a year, he must go to the wall. (175, 176, 188.)

Mr. Powers says the manufacturer and miner have the same competition to meet in foreign markets that the farmer has, but in so far as they produce articles which are not produced in sufficient quantities to supply the home demand, and on which there is an import duty, the price is not wholly fixed in the world market, and they have a margin of advantage. (176.)

Mr. GEORGE says the prices of agricultural products are fixed by competition with the products of the world in foreign markets, though there are some causes in operation in this country affecting prices unfavorably, which might be remedied by legislation. Our surplus is usually large enough to make it necessary for the foreigner to fix the price in large measure. (221.)

3. **Value of agricultural statistics.**—Mr. DYE says there is too little knowledge on the part of farmers as to the demands of consumers throughout the world and the acreage of various crops. Accordingly there is often undue planting of some particular crop. To remove this ignorance the State and national departments of agriculture should give out as much statistical information as possible. Foreign consuls should be called on for reports as to the conditions in foreign countries. If the farmers, moreover, were better informed as to the probable supply of different products, they would know when to hold back their crops in order to secure higher prices. (95, 96.)

Mr. HYDE says that statistical information relative to the condition, prospects, and actual products of agriculture has the strongest influence in maintaining a reasonable equilibrium between production and demand and assuring profit to the producer. (842.)

B. Speculation in farm products.—1. **Beneficial effects.**—Mr. S. H. GREERLEY, a commission merchant of Chicago, believes that speculation in grain is a good thing, if the buyer is on equal footing with the seller, because when the price gets too low some one will take the grain as an investment. The board of trade is an institution organized for the dispatch and convenience of business. It is the system which has grown up within the board, and not a part of it, which hurts business and hurts the producer. (235.)

Mr. JUMPER, of South Dakota, has always thought that grain gambling helped the price of wheat. Up to the time of the Leiter deal wheat ran along in a rut for years. Mr. Jumper believes that the Leiter deal took it out of that rut, and the price has not been as low since then as it would have been otherwise. It was not so beneficial at the time because the farmers have but little wheat in May, but it has been beneficial ever since. (737.)

Mr. BUDGE, of Grand Forks, N. Dak., does not think dealing in options and futures hurts the price of wheat. Sometimes the producer gets the best of it; for the past 2 or 3 years the producer has had the benefit of higher-priced wheat than he would have had without the future business. The Leiter deal in the spring of 1898 helped some of the farmers; it injured some people who had a notion that the price was always going to remain high, but those who had good judgment did not get caught. The farmers always complain that wheat goes up when they have none to sell. (856, 857.)

Mr. GEORGE says corners are sometimes run apparently in the interests of farmers. The Leiter deal is the only corner he ever saw that really helped the farmer; he thinks that helped the entire country, because wheat was sold abroad at higher prices than would otherwise have been obtained. (225.)

2. **Injurious effects.** (See also *Bucket shops and Bear speculators*, XIV., B 14, p. cccxxxiii.) Mr. BRIGHAM believes that illegitimate speculation or gambling in farm products on the exchanges tends to injure the farmer. When crops are good the

dealers have a motive to hold the prices lower than they should be. Large quantities of grain are offered which do not really exist, and foreign markets may be influenced by the impression that real grain is available in such quantities. Such fictitious grain also may be nominally sold to those in league with the speculators at prices lower than the supply would warrant. It is of course impossible to keep prices down long when a real shortage exists. The handling of grain on margins especially tends to injure the market. The sale of actual grain is not to be considered gambling. The witness understands that warehouse and insurance charges are often paid on fictitious grain, and this burden must ultimately fall on the farmer. The fact that oats, corn, and barley are less subject to gambling explains the fact that their prices are more satisfactory than the price of wheat.

The witness does not desire to stop legitimate speculation, and recognizes the difficulty of distinguishing properly between it and grain gambling. Future sales and option sales are legitimate, but "puts" and "calls," especially those dealt in outside of the exchanges, should be suppressed. Many of the legitimate dealers of the exchanges supported the bill before Congress for prohibiting such practices.

The States are unable to legislate satisfactorily on this subject. Congress can probably act under the authority to tax. The right of Congress under the interstate-commerce clause of the Constitution is more doubtful. The National Grange took an active part in pushing the Hatch bill before Congress, and is strongly in favor of Federal legislation on this subject. (24-26.)

Mr. DYE also is of the opinion that "grain and cotton gambling" is injurious both to the producer and the consumer. Although there are bulls as well as bears on every market, the tendency is to depress prices at the time of harvest, even though they may be kept up later on. The offering of fictitious grain must have this influence. The farmers do not secure correct information, through the speculators or in any other way, to enable them to know what the prices of their products should be and to hold them back when desirable. (97.)

Mr. NORRIS, master of the New York State Grange, thinks dealing in futures has a very bad influence on prices, and ought to be regulated by stringent laws. If a man buys 10,000 bushels of wheat and controls 50,000, the tendency is to make fictitious values, keep up an unrest in prices, and affect the producer injuriously. (331.)

Mr. WILSON says the farmers of Illinois have no objection to the legitimate work of the board of trade, and realize that it is a necessity; but they think there is no advantage in selling more wheat in Chicago in a day than is produced in the United States in a year, and that the manner in which the speculation is carried on at present depresses prices as a rule. When the price is raised by manipulation on the board of trade it seldom affects the farmer. At the time of the great corner grain was sold in Chicago 35 cents higher than it was sold the same day in Magnolia. The farmers call this gambling, and have never been able to see where it benefited the producer, though members of the board of trade have tried to show them that it increased the price of their products. Mr. Wilson thinks the large elevator men very largely control the price of wheat in Chicago. (253, 254.)

Mr. MORAN, president of the National Grain Growers' Cooperative Association, desires the abolition of trading in futures, as one of the greatest influences destroying the value of farm products. In particular, he desires the abolition of bucket shops as a destroyer of values. Mr. Moran says his association has no objection to the buying of grain to be delivered at a future date, provided it is actually delivered, but objects to the selling of millions of bushels of wheat where never a bushel changes hands. Every bushel of "wind" wheat put on the market has a tendency to depreciate the price, by giving foreign buyers the impression that there are immense volumes of wheat in the elevators. (720, 723.)

Mr. GRAHAM, president of the North Carolina Farmers' Alliance, has no doubt that dealing in futures has much to do with the low price of farm products, and believes that the Government ought to treat such dealing as it did the lottery. (435.)

Mr. WEDDERBURN believes that the effect of dealing in options and futures is absolutely ruinous. If a man has a right to sell something he does not own and never expects to have, in competition with actual wheat and at a lower price, it is bound to bring the price down. The selling of many times as much wheat as is raised, for delivery at future dates, makes it necessary for the men who have to deliver the wheat to work to keep the price down. Mr. Wedderburn does not believe the opposing attempt to keep the price up works. He says a report of the House Committee on Agriculture in the Fifty-second or Fifty-third Congress covers the whole subject in the most admirable and thorough manner. (632.)

Mr. HALE thinks speculation in grain and cotton is an injury to the producer. (399.)

Mr. PEEK believes dealing in futures to be a great drawback to the farmers, "and

it keeps things unsteady." He thinks the prohibition of gambling in futures would help the farmers. (461.)

Mr. STEVENS, Commissioner of Agriculture of Georgia, says grain and cotton gambling has been very harmful to the farmers of the South and to industry in general. He believes that if all gambling in futures could be suppressed the price of commodities would advance, and the farmers would be in a much better condition. (916.)

Mr. GEORGE thinks it just as possible for a combination of large capitalists to bear the market—that is, to sell whenever there is any tendency for prices to advance—as to bull the market, and perhaps easier. He thinks that in years of comparative plenty prices are depressed too far, and that prices are often depressed by the elevator men from September to January, when most of the farmers are compelled to sell their grain. Many dealers buy farm produce to carry in cribs, as well as to fill up their city elevators. (225.)

Mr. PROM, a banker and farm owner of North Dakota, thinks gambling in "wind" does the farmers harm; it sometimes increases the visible supply artificially, and therefore lowers the price where the supply does not exist. The future sale of actually delivered wheat does not affect the spot price, but "those sales and purchases are made by men who never saw wheat and who have no wheat to sell." Mr. Prom thinks it would be better for the farming community if the practice were prevented. (794.)

Mr. BROWN is of the opinion that dealing in options and futures has a tendency to demoralize the prices of cotton, and on the whole to depress them. Forty, 50, or 100 times as much cotton is sold in a week on the exchanges as is raised in a year, and this apparent greater supply naturally reduces the price. The witness does not see the necessity or desirability of future sales, enabling the manufacturer to buy cotton before it is raised. (74.)

Mr. LOVEJOY believes that the excessive production of cotton in the South doubtless has some tendency to keep prices down, but that speculation on the exchanges has fully as great an influence. Nineteen out of 20 deals on the exchange are fictitious, and the apparent supply is much greater than the real supply. The witness further believes that there is something in the nature of a combination among buyers in the Liverpool markets to fix prices, the comparative absence of fluctuations within the year pointing somewhat in this direction. (75, 76.)

Mr. MILLER, secretary of the Ohio State Board of Agriculture, says that at times values are undoubtedly enhanced or depreciated by dealing in options and futures, but is not prepared to say that they affect the farmer injuriously in the long run. (615.)

Mr. BARRETT does not believe that speculation on the exchanges has the slightest effect on the price of cotton. (58.)

Mr. HAMMOND, a cotton planter of South Carolina, thinks that speculation probably has a steadying effect upon prices, but it is demoralizing to the planter, because he is led to take part in it. The people of the South are losing more by betting on cotton than by producing it. (831.)

3. *Relation between spot and future prices.*—Mr. PRATT, of Aberdeen, S. Dak., thinks the sale of "wind" wheat has no effect on the spot price. He admits that the Leiter-Armour deal had some effect on the price of wheat, but not as much as it might have had, because the buyers had been grading so liberally that they could not get the same grades at Chicago. (728, 729.)

Mr. JUMPER thinks the price of "wind" wheat has much to do with the actual price of wheat on track and the price paid to the farmers. (730.)

Mr. Jumper says the price of wheat on track in Minneapolis is usually from 1 to 3 cents less than the distant future, but sometimes when there is a scarcity of wheat the cash price in Minneapolis will be higher in January than the May price. (731.)

4. *Hedging by millers.*—Mr. POWERS says the city men who handle actual wheat do less speculation than is popularly supposed. The great mills of Minneapolis, when they buy wheat in the fall, protect themselves against fluctuations by selling a future against it and buying it back when they grind the wheat. The price at which they sell the flour will be governed by the price at which they buy the option. They are certain that in the long run the variation in the price of wheat will cause more loss than profit, and they make some one else carry the risk. A few years ago the Chicago speculators used these futures to squeeze the Minneapolis millers. They manipulated the grain inspection in Chicago, and would not take No. 1 Northern, the Minneapolis grade, as equivalent to No. 2 Chicago, and so forced the price up. (190.)

5. *Proposed legislation.*—Mr. S. H. GREELEY, of Chicago, believes that there should be national legislation affecting railroads, bucket shops, and public warehouses, which would make it impossible for bucket shops to exist. (235.)

5. Mr. MORAN says a law should be enacted to prevent gambling or option dealing in

grain. He believes that it would be to the interest of the farmers to have both the bucket shops and the boards of trade stop selling options. Gambling in grain is detrimental to the farmers' interests. (723.)

Mr. MILLER's personal belief is that dealing in options and futures is not a crying evil requiring serious attention, but he does not claim to represent the average agriculturist of Ohio in this opinion. He has never had any particular confidence in legislation for controlling such dealings. (616.)

C. Prompt and deferred sales.—1. Wheat.—Mr. HANLEY says the necessities of the farmer oblige him to market his grain at the time of the year when the great volume of grain is being thrown on the market. The farmer himself assists in breaking down the price of his own products and plays into the hands of the speculators, who juggle the prices so that they are generally lowest when the farmers are parting with their grain and highest when the farmers have no grain for sale. The farmer finds himself at the mercy of the greedy and unscrupulous grain buyers, who rob him on grades and dockage. He has no means of intelligence from the General Government except that which is often used against his interests by speculators. (286.)

Owing to lack of storage room and their pecuniary circumstances, Mr. JUMPER says, a large percentage of the farmers are compelled to sell their grain within 3 or 4 months of thrashing time; not more than 60 per cent of them, however. Mr. Jumper thinks the averages show that the price is generally lower during these months than at other times. The best time to sell wheat, however, is immediately after thrashing; the experience of every farmer is that he gets the best price immediately if he can get to the market first. If he keeps his wheat 6 or 8 months he ought to get 3 or 4 cents advance, but there is a loss by mice and rats and shrinkage in the granary or warehouse, besides the expense of putting it away and taking it out. (736, 739.)

Professor DAVENPORT says an assistant of his once made a study of the best time to market wheat, considering interest on its value, damage by rats, etc., and found that in the previous 20 years there were only 2 or 3 years in which the farmer would have gained anything by storing his grain 2 or 3 months instead of selling it as soon as it was thrashed. (273.)

From an examination of the wheat prices in Chicago, the greatest speculative market of the world, and in Minneapolis, the greatest market for the handling of actual wheat, Mr. POWERS finds that by buying cash wheat the first of September and holding it in storage until the first of May one would lose on an average 2 cents a bushel. Throughout the Northwest the boards of trade have their prices in the fall nearly always raised 2 cents above the average which the situation the following spring will justify. The farmers and those associated with them are always bulls on the market. As a rule, the expectation of a rise is not realized, and taking the last 30 years as a whole, the farmer selling his wheat at harvest receives 2 cents a bushel extra, which comes out of the speculators. A great many options are purchased by farmers and persons who live in the country, who always think there is going to be a higher price than is actually realized. (190.)

Mr. PROM, of North Dakota, says nearly all the farmers sell within 3 months after thrashing. He thinks 75 per cent of the grain is sold at once. Ordinarily there is no advantage in holding the grain. The average price during the 5 months from September to January, inclusive, varies less than a cent. The only probable advantage would be to hold the grain until June or July, and by that time the wheat will be shrunken and the demand reduced. (800, 801.)

Mr. PRATT, of Aberdeen, S. Dak., says the farmer, instead of selling his wheat in September, can store it and borrow money on the receipt, and so carry the wheat. The bank at Aberdeen is very glad to get these local wheat checks. Mr. Pratt is of the opinion that early sales are best, however, even if the farmer has his own granary. Mr. Pratt says he has tried both ways and thinks it better to sell direct from the machine. Those who pursue that course have the money to use, and there is no shrinkage and no loss. No man can tell the future of grain. (728, 729.)

Mr. BUDGE, of Grand Forks, N. Dak., says that in the fall the price is generally best at the beginning. In about 6 weeks the market may drop off, or it may go up. The farmers generally will not sell when the market goes up; they wait until it goes down. Mr. Budge has never seen any indication of any combination to control the price when the bulk of the wheat is coming in, except that the price generally goes down when there is a rush of cars going into Duluth. (856.)

2. Cotton.—Mr. MOSLEY, a cotton dealer of Memphis, believes that there has been a fluctuation from one-fourth of a cent to 2 cents a pound each season for the past decade. His impression is that the average price is lowest between the latter part of November and the 1st of January, when the bulk of the crop is being marketed and

the receipts are largest, and when buyers are therefore in no hurry to buy. The great trouble with the cotton market in Memphis is that the cotton is rushed into the markets in immense volumes in the fall; the farmers have obligations that compel them to unload their cotton. (515, 516.)

Mr. WHITE says a great many farmers in North Carolina hold their cotton for the rise in the fall, but a great many have to sell as fast as they pick it to satisfy their obligations. (419.)

Mr. BARRETT says that the practice of giving crop mortgages on nearly the entire cotton crop forces it to be placed upon the market within a short time in October, and greatly depresses its price. The average amount received by the farmers of Georgia for their cotton in 1898 was a little over 4 cents a pound on the farm. (50.)

Mr. NUNNALLY, of Georgia, testifies that he sold his cotton in one lot in February, 1900, at $7\frac{1}{2}$ cents. He says that not one in ten of the farmers in his locality are able to hold their cotton. The farming is done by small farmers on one or two horse farms, on the tenant system. (454.)

Mr. PEEK, of Georgia, testifies that 90 per cent of the farmers are compelled to sell their cotton in the fall, and that the price always goes up after the cotton is in the hands of the broker. (458, 461.)

Mr. GODWIN, of Tennessee, says a great many people who are not pressed for money will take their cotton to market, not caring to take the risk of having it about home. (476.)

Mr. KYLE says the tenants of Mississippi do not generally hold their cotton for an advance, but he estimates that not more than 25 per cent of the farmers are compelled to sell their cotton immediately after harvest. Some landlords take the crop of their tenants at market prices and dispose of it later, but he himself has never held his cotton. He thinks, as a rule, the prices are as good at the beginning of the season as later. (470, 474.)

Mr. GRAHAM, president of the Cotton Growers' Association, says the association is endeavoring to make arrangements so that farmers can hold their cotton crop. The price of cotton was at a very good figure at the date of Mr. Graham's testimony (March, 1900), but the farmers had nearly all sold out at the close of the crop. (433, 435.)

D. Middlemen.—1. *Relation to prices.*—Mr. WILSON thinks that the cost of transportation is too high, and that there are too many middlemen between the producer and the consumer of farm products. He thinks the consumer is paying about what he should pay, but it costs too much to handle the grain. (249.)

Mr. POWERS says that in the years 1870 to 1874 it cost from 1 to 2 bushels of wheat to take 1 bushel to Liverpool. The farm problem was the elimination of the middleman. The farmer reasoned that he ought to have one-half the benefit of the elimination, and the purchaser in Liverpool the other half. He thought there would be an advance in the price of wheat in Iowa equal to one-half of the change in the cost of transportation. To-day it takes only a little more than half a bushel of wheat to take a bushel from Iowa to Liverpool, but so far as the price of wheat is concerned, the Western farmer has gained nothing by the elimination of the middleman. His gain is found in the decreased cost of the goods he purchases. The purchaser of any article will always get the benefit of any economies in its manufacture, transportation, or handling. The price of wheat is substantially what it was in the early seventies. (181.)

Mr. HOLMES says farmers are so numerous that they are subjected to severe competition with one another in the disposal of their products, and are naturally at the mercy of middlemen probably more than any other class of producers. The farmer, being isolated and lacking capital, is unable to reach the consumers direct; the middleman buys from him practically upon commission, thus compelling the farmer to supply the capital for his operations, and making him suffer for losses by bad debts and other causes, to say nothing of the frequent dishonesty of the middleman and his false reports as to the prices received. The tobacco buyers visiting a certain neighborhood are perhaps in tacit or express agreement as to the prices they will pay, and as the individual farmer can not reach a tobacco warehouseman or manufacturer, he is compelled to accept what the buyers offer. The position of the farmer acting alone is economically weak, and one of the reasons why he is discontented is because he has fought the battles of production and trade single handed. (158.)

Mr. Holmes adds that agriculturists can not get along with the middleman, who is a necessary link between the producer and the consumer in all industries; but he would like to see the farmer become his own middleman. (162.)

Professor DAVENPORT thinks there is still the feeling among farmers that in the sale of their products there are too many middlemen. He thinks that wheat at 60

cents a bushel is hardly compatible with bread at 5 cents a loaf and bran at \$15 a ton. (268.)

2. Grain buyers.—Mr. GEORGE says that in marketing their grain, in order to save the middleman's tolls, the farmers come in contact with the grain buyers, who have State associations and a national association, and in a measure control the prices of the grain. (224, 225.)

3. Commission merchants.—Mr. MILLER says the shipping of Ohio grain to the seaboard is done almost entirely by commission men, the farmers getting the going rate for their grain where it is sold. The merchants say openly that they have to protect themselves against the possibility of being "held up" by taking more than would otherwise be necessary. (616.)

Mr. KETCHUM testifies that commission men in New York often buy the goods sent them at the market price, in the case of articles that can be held. In reply to the suggestion that farmers might choose men of their own class to buy and sell for them, Mr. Ketchum intimates that they might become as bad as the original commission men. (137.)

Mr. CLOHAN, a fruit grower of West Virginia, says he knows some commission merchants who are men of the very highest honor and integrity, but shipping to commission houses is very uncertain. He thinks they have favorites, perhaps in the canning houses, and will often unload a car of fine fruit as being damaged. Mr. Clohan once shipped to Pittsburg, at a time when he expected a drop in peaches, 100 crates on Monday and 50 crates the following day. The returns from the 50 crates were \$1.50 a crate, and for the 100 crates about 40 cents. He was notified that the 100 crates had arrived in the glut, but he was satisfied that there was something wrong.

Mr. Clohan thinks the solution is to hunt out a commission man thought to be thoroughly honest and trust him implicitly. It is not wise to change the market frequently; if some other merchant offers a big price he is going to make it up. (597.)

4. Cotton factors and brokers.—Mr. PORTER, a cotton broker of Memphis, testifies that he buys almost entirely from factors; that is, commission merchants. The farmer ships to the factor for sale on commission; the factor takes samples and spreads them out on his table, and the broker buys from him and sells to mills in New England, Canada, and Europe. Mr. Porter prefers buying from the factor rather than from the farmer, because it is less trouble. He says it is undoubtedly an advantage to the farmer to employ a factor. The cotton factor's commission is $2\frac{1}{2}$ per cent, and he frequently makes more than the broker, his profit being certain and the broker's very doubtful. (480, 481.)

Mr. Porter says the cotton brokers sell on firm orders, at a certain price landed at the mill, and make what they can out of it; they have to calculate freight, drayage, etc. Competition is so keen that their profit is practically a fixed brokerage. (482.)

E. Local markets.—1. **Importance of home markets.**—Mr. KETCHUM, of New Jersey, thinks the American farmer is dependent upon a good home market. In selling to foreign countries he competes with the cheap labor of those countries. An increasing city population benefits the farmer by increasing his market. (135, 136.)

Mr. POWERS says the capacity to consume is a factor slowly modifying prices, having far greater influence with certain articles than with others. The amount of bread and breadstuffs used for human food varies but little, but the consumption of strawberries and other fruits may increase enormously with but little decrease in the consumption of other things. Minneapolis, as a center of consumption and distribution for the Northwest, has shown a doubling of fruit sales once in 3 years, or 8 times as fast as the population. The amount of canned fruits, vegetables, fish, and meat consumed in this country, measured in quarts and pints, is very great, being equal to the total consumption of alcoholic liquors, though canning began only about 1865 or 1870. The relief of agriculture must come partly from an increased consumption of these things, which represent a relatively large amount of labor. The increased demand for these luxuries in the United States means about as much to the farmer as increased exports. (186, 187.)

Mr. STOCKWELL says home markets are the sources upon which New England agriculture must rely for its profits. The more people and industries and the more prosperous the industries, the better it is for those who furnish the home-market products. The laborers of New England are the consumers. They usually have large families, and the farmer and the market gardener are the gainers. This diversifies agriculture and draws it into more profitable channels. The old lines of agriculture have passed away near these centers of population; it is the market garden and improved methods that are now profitable, and because of this agriculture is more profitable in New England—certainly in Massachusetts—than a few years ago. (886.)

Mr. BATCHELDER also says that the New England farmers are almost altogether dependent upon local markets; they export very little. The vegetables, fruits, etc., raised in New Hampshire are mostly used in the cities of that State. Whatever legislation is possible to increase the local markets will be of benefit to the farmers. (40, 42.)

Mr. PROM thinks a man engaged in manufacturing in Chicago would consume more Dakota farm products than one similarly engaged in London. The American laborer lives better than the European, and the latter buys his agricultural supplies from several countries. (794.)

Mr. WEDDERBURN thinks the horticulturist, dairyman, poultryman, and vegetable farmer probably have an increasingly valuable home market, by reason of the large manufacturing, mining, and transportation industries of the country; but that the men who produce wheat, corn, cotton, and tobacco have not, because the prices are fixed at Liverpool, and the surplus fixes the price. The prices of products which are not exported, such as butter, eggs, cabbages, etc., are fixed at home. (629, 630.)

Mr. SPEAR says the main market for Vermont farm products is Boston. (407.)

Mr. COLES, of Salem County, N. J., says the main bulk of agricultural products from his section goes to or through Philadelphia, though some shippers ship to New York and Boston and along the Delaware River. Early potatoes and watermelons are shipped all through northern Pennsylvania and New York, as well as to Boston. (127.)

Mr. PROM says the North Dakota farmers can not sell their grain in North Dakota; that is the great trouble with them. The increase of population of Western towns and cities would not help the grain market so much as it would aid the farmer in diversifying his crop, and in raising chickens, garden truck, sheep, and stock. Mr. Prom does not see how manufacturing can develop in North Dakota because of the absence of fuel and power. (794.)

2. Need of facilities for direct marketing of products.—According to Mr. DYE, secretary of the New Jersey State Board of Agriculture, a special need of the farmers is that city authorities should provide better facilities for marketing truck products directly by the owner. At present the poorer classes in the cities have to get their vegetables largely from hucksters, and they are accordingly often stale and unfit to eat. Direct marketing by the producers is difficult because of the large number of hucksters and other dealers. (91.)

F. Cooperation in the marketing of products.—**1. Need of organization.**—It seems to Mr. WHITNEY that the introduction of business methods and organization in the marketing of crops is one of the most important factors in the reclamation of abandoned lands and the introduction of new crops. The success of the truck industry at Norfolk is largely due to the splendid organization of growers and to the way in which truck farmers place their crops in certain markets according to the demand, an essential thing in truck farming, because vegetables must be sold as soon as they reach maturity for whatever they will bring. The organization gets daily returns of the market conditions in different cities, and is able to divide the crops and ship them accordingly. (878.)

Mr. Whitney calls special attention to the necessity of considering the possibility of marketing fruit. The problem has been solved to a considerable extent by marketing it in a dried and canned condition. The exportation of dried fruit is increasing in importance, especially on the Pacific coast, where large quantities of fruit are being consigned to China and Japan. (877, 878.)

Mr. REDDING says there is need of cooperation and education to show the farmer that he should not sell his products for less than a fair market value. The butchers in Georgia pay 2½ cents a pound for steers and sell them for 4½ to 5 cents, or 6 or 7 cents for dressed beef. (447.)

Mr. AGER suggests that the prices of farm products might be controlled in some instances by combinations of farmers shipping to certain points. He thinks the formation of a trust to regulate the prices of farm products would be a good thing for the farmers, but is the last thing they would be able to accomplish. It would be the worst trust in existence, if it could be formed, because people have to have something to eat. The Grange has never formally discussed the formation of a trust. (111.)

Mr. HALE says there is a combination among part of the fruit growers in Georgia, but it has not been of very great assistance except in bringing them together and getting them acquainted. There is need for cooperation in distribution, especially among the smaller growers. To get the best service they must be able to load full cars promptly and ship promptly. (399.)

2. Milk Producers' Union.—Among the associations of farmers, commonly termed coop-

erative, which he deems to be virtually trusts, Mr. HOLMES mentions the Milk Producers' Union which supplies Boston with milk. The dealers in Boston have had an association for some time, and the farmers were at a disadvantage until they formed an association for the purpose of dealing through their representatives with the representatives of the Boston Milk Dealers' Union. Representatives of both organizations meet every year and agree upon prices for the remainder of the year. This arrangement is satisfactory to both parties, and the individual farmer finds himself in a much better position than formerly. (158.)

Mr. AGER testifies that there is a milk dealers' trust in New York City, formed to handle milk and get it from the dairymen at its own price. Through the influence of the American Agriculturist the farmers have formed the Five States Milk Producers' Association, with agencies at nearly every point on the lines that ship milk into New York City. They have a man in New York to tell them how much milk should come from each station, and by keeping the surplus off the market they obtain fair prices. They made a contract with the New York syndicate to furnish milk at \$1.17 per 100 pounds, whereas they were formerly getting only 80 cents, or about 2 cents a quart in summer and 3 cents in winter. The association puts up creameries and cream separators at various stations. (11.)

Mr. DYE says that in 1898 a movement was started by Mr. Myrick, editor of the American Agriculturist, to organize the "Five States Milk Association." Its aim was to combine the milk producers and to control the output of milk so that there should be no more than enough to satisfy the daily demand in New York. The project has not yet succeeded and Mr. Dye doubts if it ever will. A similar effort in Philadelphia a few years ago finally failed. (99.)

Mr. KETCHUM says the Five States Milk Association, with headquarters in New York, affects the extreme northern counties in New Jersey, but he has been told (June, 1899) that it is hardly in working order and has not yet accomplished much. (135.)

Mr. COLES, of Woodstown, N. J., thinks there is no milk trust among the farmers in his section of the State. (126.)

3. Fruit growers' associations.—Mr. HOLMES says the California fruit growers have been compelled to form a trust for the purpose of suppressing competition among themselves, getting lower freight rates, finding responsible customers, and getting remunerative prices. The fruit growers of Santa Clara Valley, for instance, have organized an exchange, with an expert manager, acquainted with the conditions of the market, to make their sales for them. Numerous fruit associations have grown up all along the Pacific coast, and they are coordinated by a central exchange in San Francisco. There is no other such immense fruit trust in this country, but there are smaller ones in Florida and in western New York, New Jersey, Ohio, Michigan, and nearly all the other fruit-growing States. The associations require cash for sales, and those which conduct a buying business do not as a rule buy on credit. Mr. Holmes does not understand that these organizations undertake to lessen the product, and does not think they have raised the price of farm products, but they have reduced the cost of transportation. The cooperative marketing of fruit has been developed to a great extent along the Atlantic coast from New York City to Florida, and on the Pacific coast it has been developed to a great extent in the truck-garden business as well as in the fruit business. (158, 159, 162, 163.)

Mr. DYE says the combinations of fruit growers in California control a large proportion of the total output of fruit. They are not in the nature of trusts and do not seek to regulate prices, but merely cooperate in shipping and in pushing the sale of fruit. (97, 98.)

Southern California Fruit Exchange.—Mr. NAFTZGER describes the Southern California Fruit Exchange as a cooperative organization of citrus-fruit growers engaged in marketing oranges, lemons, and grape fruit for its members. The fruit is marketed for all members alike on a level basis of cost. The exchange confines itself to the purchase of the necessary supplies for packing and to the business of shipping and selling. It consists of 11 members, all of whom are directors, nominated by district exchanges. The organization is a marketing agency for the local or district exchanges, which in some instances are incorporated under the cooperative law, but in most instances are regular statutory corporations. Each member contracts to leave his fruit for the season under the control of the organization, to be marketed entirely under its direction. The object of the organization was primarily to avoid the disasters of the commission system. Prior to the organization of the exchange fruit was sold to a limited extent f. o. b. California; but in a very large number of cases it was consigned to commission houses in various cities to be sold for account of the shipper. This proved disastrous to California citrus-fruit growers because of the long distance from markets, the possibility of decay, etc. The organization was effected for the

purpose of taking the marketing of the product out of the hands of the middlemen and substituting an independent system under the absolute control of the growers. The organization was incorporated in 1895. Before that, for two years, there had been a compact among the growers, and they attempted to sell f. o. b. California, but with very poor success, and in 1895 the present corporation established its own agencies to sell the fruit delivered. The goods are forwarded to the agents of the exchange, who are in nearly all cases salaried men (the exchange has over 20 salaried officers in the principal cities of the country), and are offered to the trade in the regular course of business at the best prices obtainable. The organization began with about 25 per cent of the crop and now has about 50 per cent, and fruit growers are still steadily joining. With 50 per cent of the crop beyond its control it is not able to control the distribution of the fruit; but being able to put a liberal supply in any market at any time, it can exercise a very powerful influence over the conditions of the market. The exchange does not have any of the ordinary features of a trust. It does not attempt to control production in any way. Independent producers still reach the markets through their own brokers.

Some of the agents sell, under the direction of the exchange, dried fruit and canned fruits for other cooperative associations of growers; but this business is not under the control of the exchange in California.

The advantages accruing to the producer from the exchange are that they get their fruits sold at better average prices and sustain smaller losses than under the commission system. Before it was organized the fruit was handled in a haphazard manner through commission men, and in very many cases the grower, guaranteeing all charges, came out in debt, as sometimes still happens with those who contract with commission firms. Values were depreciated and the fruit-growing industry was in a very bad condition. It is now in a sound condition, though it has its fluctuations like any business in agricultural products.

Through the association every sort of information is given to the growers as to what is desirable in the markets, the class of fruit, character of package, manner of handling, etc., and thus, to a certain extent, influences are brought to bear on the growers to do good work. (945-948.)

Mr. Naftzger says most of the local associations have what they call a Christmas pool of oranges, or a monthly pool of oranges or lemons, although some associations pool for the whole season. If it is a monthly pool, the manager of the association will send out notice to the growers who are members of the association to bring 10 or 15 per cent of the crop, as the case may be. The fruit is brought into the packing house and a ticket is issued for it. The fruit is then culled and graded as to whether it is fancy, choice, or standard. When the fruit of that month's pool has been marketed, the money is distributed pro rata among the growers who were in the pool. All members have the opportunity to go into every pool and get the advantage of all markets at all seasons on a level basis. They may agree among themselves as to separate pools, or they may agree that each man's fruit shall be handled for his separate account. If a man is dissatisfied with the methods of his association he can file his complaint and have an investigation, or at the end of the season he can go into another association; but there are very few complaints. (960.)

Mr. Naftzger testifies that the exchange is organized with a nominal capital stock of \$10,000. It has no capital paid up except what it has in office furniture and fixtures, amounting to a few thousand dollars. It buys nothing but packing materials for the local exchanges, who pay for them on delivery, and requires little or no capital. At the end of each month the local exchanges are called upon to pay for what is estimated to be the expenses of the month, and the accounts are adjusted at the end of the season, all fruit being assessed alike for the actual expenses of operation. (948.)

Mr. Naftzger doubts whether the effect of the exchange has been to increase the price to the consumer at all. The object in organizing was to save the losses and lessen the expenses between the producers and consumers, and to create a wider distribution and consumption of the product. With the increase of the product the level of prices falls from year to year. (949.)

Other fruit associations.—Mr. NAFTZGER testifies that there are 2 other cooperative organizations in California dealing in prunes and raisins. The Cured Fruit Association devotes itself chiefly to prunes, the Raisin Growing Association entirely to raisins. These associations are similar to the Southern California Fruit Exchange, except that they undertake to establish an arbitrary price f. o. b. California. Previous to the organization of these 2 companies the prune and raisin trades were both in a very bad condition. The raisin association, having operated some 3 years under its present form, has done a very good business. The prune association began operations in 1900, and has had very great difficulty. There was a large quantity of the

product which it did not control, and the establishment of prices f. o. b. California enabled the outsiders to shade the association price. Mr. Naltzger regards the attempt to fix an f. o. b. price as impracticable and as the source of the difficulties of both these associations. He believes the products must be marketed at whatever price the consumers will pay. (948, 949.)

Mr. TURNBULL says that there is at San Jose what is called the California Cured Fruit Association. He believes it handles only raisins and prunes. Of prunes it handles about 3,000,000 pounds a year. It is said to fix a price on prunes and to refuse to sell them for less. The condition of the prune and raisin industries was very low before the association was formed, and now the raisers are doing fairly well. Mr. Turnbull believes the association sells its goods through its own agencies. (984.)

Mr. HALE says there is a peach growers' organization at Deckertown, Sussex County, N. J., that has marketed the crop to fairly good advantage. He also refers to a similar association at Hammononton, N. J. (399.)

4. Difficulties of cooperative fruit selling.—Mr. CLOHAN says it is hard to combine in the shipping of fruit, because the farmer is no more honest than anyone else, and some farmer may put his knotty and wormy fruit into the car. The selection of the fruit is a difficult thing to arrange. (597.)

G. Various matters affecting farmers.—**1. Need of economies in production and distribution.**—Mr. HOLMES says that in order to hold his footing in the face of declining prices the farmer has needed to depend upon (1) reducing the cost of production, (2) cheap transportation facilities, (3) an increase of product, and (4) combinations to keep up or increase farm prices. (156.)

2. Farm accounts.—Mr. FLANDERS, Assistant Commissioner of Agriculture of New York, says that some of the farmers of the State, especially the younger ones who have been educated at the agricultural college and many who are taking the advice of the institute workers, keep accounts with their crops, so that they know at the end of the year whether they are profitable or not. Many are learning to apply tests periodically to the milk of each cow, so that they know which cows are returning a profit and which should be got rid of. (995.)

Mr. NORRIS, of Sodus, N. Y., says a system of time cards is used in that section; at the end of the month the foreman charges up the work done by every man and horse on the farm, showing just what is charged to each crop. Mr. Norris believes the nearer farmers come to a correct system of accounting the better they will do. As a rule the farmers in his section know how much money they put into their business. (321.)

3. Agriculture by amateurs.—Mr. FLANDERS, Assistant Commissioner of Agriculture, New York, refers to Briarcliff Farm as one of the many that are run by men who spend upon them money which they make elsewhere. He does not say they are generally unprofitable, but they are run rather for pride than for financial gain. A number of them do not pay. (998, 999.)

4. Farmers' purchases.—Professor DAVENPORT does not think the farmers feel the prejudice against the middlemen from whom they buy that they did 20 years ago. The large merchants have sought out the farmers, have sent traveling men to them, and have dealt with them directly. The farmers come into direct relations with the manufacturers, and have learned that their local dealers will order goods for them in large cash orders at rates considerably below the retail price. He thinks the farmer pays cash more than formerly and buys in larger quantities. (268.)

XIII. TRANSPORTATION.

A. Relation of transportation to agriculture.—**1. Effect of freight rates on land values.**—Mr. WHITNEY says the value of farm lands is often controlled to a considerable extent by the rates of freight locally applicable. The building up of agricultural industries in certain localities may be prevented by the impracticability of marketing the products profitably on account of the distance or expense. The products of Florida have to be rushed to the Northern markets on the fast freight or passenger schedule in ventilated refrigerator cars and placed on the market in the shortest possible time, and it requires a very close calculation in many cases to determine whether it is possible to send a crop North with any profit. The development of the truck industry in southern Maryland was very great a few years ago, but the product had to be sent by river steamers to the Northern market, and the transportation service was so irregular and the time consumed in getting the crop delivered at Baltimore, Washington, or Philadelphia became so great that the industry was given up on large areas for that reason. (865.)

CCXCVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

2. Development of new territory by railroads.—Mr. BUDGE, of Grand Forks, N. Dak., states that 20 or 25 years ago what is now North Dakota was little less than a portion of what was formerly known as the American Desert. The Indian and the buffalo roamed at will over the western part of the Territory, where intelligent citizens are now tilling the soil, raising stock, mining coal, etc. The cause of the transformation Mr. Budge finds in a large degree in the developing power of the railroad systems. The companies realize that the welfare of the people is their welfare, and do whatever they feel they can reasonably afford to do toward developing the country by extending branches, fostering industries, affording reasonable shipping facilities, and granting fair rates of shipment. Branches are often operated at little or no profit. Increased equipment and fast trains make it possible to handle the enormous amount of grain on the short notice which is necessary under present conditions. Rates on the leading products have been steadily reduced until now wheat is carried from Grand Forks to Duluth for $8\frac{1}{2}$ cents a bushel. Twenty years ago it would have cost 17 or 18 cents. (843.)

3. River navigation in North Dakota.—Mr. BUDGE says river navigation has not developed to any great extent in North Dakota, because there are only two rivers of sufficient size to warrant the use of boats—the Red River of the North and the Missouri. The navigation is carried on by small flat-bottomed steamboats and freight barges, and for years considerable freight has been carried on these two rivers. On the Missouri the freight is very diversified, building materials and provisions coming in and grain and coal going out. The chief impediments to navigation are the sand bars, which are formed because of the shallow water and wide banks. Before the railroad reached the Red River Valley there was considerable freight of all kinds carried by boat from Fargo and other points, but since the railroads began operating the river freight has been reduced to little else than grain. Mr. Budge gives a statement of the amount of grain handled annually by the Red River Transportation Company, which does about two-thirds of the shipping on that river, from 1895 to 1900, inclusive, showing that it varied from 217,354 bushels in 1897 to 510,375 bushels in 1899. In river transportation the same rates prevail as by rail, and many points are reached more easily than by rail. (844, 845.)

Needed river improvements.—Mr. Budge says the channel of the Missouri River should be dredged and provided with a series of pile bars, similar to those placed in the Upper Mississippi, to confine and narrow the stream. This would extend the river navigation, develop the adjacent country, and prevent destructive floods. A series of bars and locks on the Red and Red Lake rivers would also not only aid navigation but would prevent disastrous floods and be of value as a sanitary precaution, since in the late summer and fall the stream is very low, sluggish, and charged with impurities. Many towns which depend upon the river for water have suffered from this cause, and Grand Forks was forced to put in a filtering system. A series of locks and dams would be comparatively inexpensive, because the banks are generally high enough and the river channel is very narrow. Mr. Budge submits a statement showing the fluctuation in the flow of the Red River of the North in each year from 1896 to 1900, inclusive. (844, 845.)

4. Electric railways.—Mr. SPEAR, of Vermont, predicts that the building of good roads and electric roads through that State, doing away with much of the isolation of farm life, will be an important consideration in the next 20 years. (402.)

Mr. MAGIE says there are no electric railways running into the country from Elizabeth and Newark which can be used for shipping (June, 1899), but the question is being agitated. One can travel by trolley all the way from Elizabeth to Passaic. (101.)

The machinery of the street railways in cities after midnight being practically idle and the streets practically vacant, Mr. DODGE recommended in 1891 that these roads be extended and authorized and required to carry perishable food products to market. The cars could be brought up to the city limits in the daytime and held there until about midnight and then taken through the streets of the city to the various markets, commission houses, etc. Mr. Dodge hoped that this system would be introduced by public enterprise and aided as the canal system was, but he now thinks it should be done by private enterprise. (701.)

While a member of the Ohio legislature Mr. Dodge had a law passed authorizing the use of electric railway tracks for the carriage of farm products. He maintains that the owners of abutting property ought not to have power to forbid the use of the streets for this purpose. He thinks the experiment has succeeded very well in the city of Cleveland. (702.)

The difficulty with electric trolleys, according to Mr. Dodge, is that they require too expensive a central plant where there is comparatively little traffic; it is necessary to have a vehicle containing its own power. Various machines propelled by other

power than electricity have been developed, but the first great trouble was their excessive weight. A heavy vehicle requires a heavy substructure, which makes the cost of road improvement prohibitive. It is necessary to have a vehicle that does not weigh any more than it carries. (698, 699.)

Mr. Dodge says that very commonly the vehicle weighs about as much as the burden it carries, but he thinks that the improvement of roadbeds will lead to the lightening of vehicles in proportion to the load. He believes it possible to make a 4-wheeled vehicle that will safely carry 10 times its weight. He has experimented with models, and has produced a model of a vehicle for use on electric railways which will carry 20 times its weight. (693, 702.)

5. Railroad facilities for agricultural products.—Mr. PROM, of Milton, N. Dak., says the Great Northern road gives good shipping facilities in the fall, the main shipping season. A stock car can be obtained at any time. (795.)

Sheep and mutton.—Mr. GREELEY testifies that 12 years ago it took one-third more time to get a sheep from South Dakota to Chicago than it does now. There are now better facilities, better cars, and better facilities for ocean shipments. Many sheep now go from St. Paul for export. Mr. Greeley says refrigerator cars are used more by South American and Australian than by American sheep growers, and suggests that if they had not been invented American mutton would, nevertheless, go to Europe and get better prices than it does. (943.)

Fruit—California.—Mr. NAFTZGER complains that the California fruit growers have experienced an insufficiency of transportation facilities, particularly in 1900 and 1901. In 1900 the green fruit shippers were unable to market all of their product for want of transportation, and during the following winter the citrus fruit growers were unable to market all of their oranges. The railroad people themselves have estimated that 3,000 carloads of oranges were lost for want of transportation facilities. In some cases the fruit was thrown away entirely. About 200 carloads of fruit a day should go out from southern California from the middle of January until the 1st of May; but the railroads were entirely unable to haul that number. They hauled an average of about 150 cars a day a part of the time, but some of the time fell to an average of about 120 cars. The particular difficulty was a shortage of engines. Mr. Naftzger is assured by President Hayes, of the Southern Pacific, and President Ripley, of the Santa Fe, that ample facilities will be provided in the future. Ordinarily, in previous years, it took about 12 days to send fruit from California to New York, but this last year it took as long as 20 or 25 days, and much of the fruit decayed in transit. (955, 956.)

Georgia.—Mr. HALE testifies that refrigerator cars are used in shipping fruit from Georgia. Peaches are packed in crates holding 6 4-quart baskets, of which about 500 are packed in a refrigerator car. Some fruit growers have taken the cars belonging to the railroads and attempted to do their own re-icing along the line, but better service is obtained by contracting with the refrigerator car companies, who own their cars and reice them. The Southern Railroad and the Central Railroad of Georgia have given the fruit growers very fast time and charged a pretty good rate for it, but Northern rates are exorbitant as compared with the Southern's. The railroads make a special peach rate of \$265 a car to New York, which is the same to all fruit growers whether they ship 1 carload or 200. Mr. Hale estimates that the Southern Railroad brings 80 per cent of the Georgia peaches to the northeastern part of the United States, turning the freight over to the Pennsylvania road at Washington. (378.)

Mr. Hale says there is a general improvement in transportation in the South. The railroads he has come most in contact with are willing to do everything possible to foster new industries. They carry freight to New York from Fort Valley, Ga., in 48 to 50 hours. Mr. Hale complains of excessive rates on the Northern roads. On the car that goes 1,000 miles to New York for \$265 the charge is \$90 more to Boston and \$70 to Hartford, a distance of 110 miles. (398.)

Mr. Hale says the railroads make a rate on fine fruits of \$265 a car of about 24,000 pounds from Georgia to New York City, and \$90 more to Boston. Watermelons they have to carry at a very low rate or they could not do any business. Georgia fruit growers pay far more proportionately than California. (390.)

West Virginia.—Mr. CLOHAN, a fruit grower of Martinsburg, W. Va., says the transportation facilities from that section are excellent. The time is 3 or 4 hours to Washington, about 6 hours to Philadelphia or Pittsburg, 8 or 9 hours to New York, and about 12 hours to Cleveland. By wiring the fruit growers can generally learn the condition of the market and ship accordingly. Those who have large shipments use the fast freight, and the biggest growers now cut their own ice and ice their own cars, the Allegheny Orchard Company having shown that that is the best way. (596.)

Shipment of fruit by express.—Mr. CLOHAN says fruit keeps better in refrigerator cars than when shipped by express, but it is necessary to have a carload in order to ship

in a refrigerator car. It costs about 17 cents a crate to ship fruit to New York in refrigerator cars, while by express, without refrigeration, it costs from 50 to 60 cents. The difference between the two rates is a great deal more than the profit, so that whatever can not be sold in the local market might as well be thrown away. Mr. Clohan declares that this is the greatest drawback to the small grower. The fruit growers are attempting to overcome the difficulty. Eight or 9 have planted some 40,000 trees at the same time with the intention of cooperating and shipping by the carload when the trees bear. (596, 604.)

Mr. Clohan says there are two express companies doing business in his locality. At one station where there is only one company the rate on fruit is 10 cents less a crate than a few miles away where there is competition. Mr. Clohan has sometimes hauled his fruit 12 miles to get the advantage of the lower rate. He explains the discrepancy on the supposition that the two companies make an arbitrary tariff and agree not to cut rates. The general opinion among the farmers is that the express rates are excessive and unreasonable. (603.)

Refrigeration rates.—Mr. NAFTZGER says fruit is shipped from California in privately owned refrigerator cars, operated under contracts with the railroads. The railroads get the cars at practically no cost to themselves, and permit the car lines to make an excessive tariff which the railroads collect from the shippers for them. This condition of things has been attacked before the Interstate Commerce Commission, and the case was pending at the date of Mr. Naftzger's testimony (June, 1901). The existing contracts expire in the autumn of 1902, and the railroad managers promise that they will not be renewed. During the life of the present contracts there have been 3 refrigerator car companies—the Santa Fé Refrigerator Line, more or less under the Santa Fé Railroad itself, which owns part of the cars and leases part of them; the California Fruit Express, owned by Mr. Earle, the head of the Earle Fruit Company, and the Fruit Growers' Express, owned by Armour & Co. The California Fruit Express was recently reported to have been sold to Armour & Co., but it was still operated as a separate line at the date of Mr. Naftzger's testimony. These refrigerator cars are operated in the fruit and vegetable business exclusively, except on the west-bound trip, when they are held for loads of other freight.

The refrigerator line agree to furnish the initial carriers certain numbers of cars, the carriers paying nothing for the cars for deciduous fruits, and the car companies maintaining the cars and paying insurance and taxes, and getting no mileage until the cars reach the terminal of the Southern Pacific or a corresponding point on the Santa Fé. In the citrus fruit traffic they get three-fourths of a cent a mile, the usual refrigerator mileage one way to these same points. After leaving these points, or getting onto connecting lines, they have the usual rate of mileage. The refrigerator cars get their compensation out of an excessive refrigeration tariff which the railroads collect as part of the expense bill and pay over to them.

A car going from Los Angeles to New York on the Southern Pacific is refrigerated first at Los Angeles, again at Truckee or Boca, at Ogden, and once between Ogden and Chicago, or at or near Chicago, and possibly once between Chicago and New York, depending upon the weather and the amount of ice in the bunkers at Chicago. For deciduous fruit, which is shipped in warmer weather, more frequent icing is required, and the rates are much higher than on citrus fruits.

The refrigerator tariff made by the car companies is graduated. In the case of citrus fruit, the first rate, covering Western points, is \$50; the rate for icing the cars from California to Chicago is \$75 a car; the maximum rate to Boston and New England points is \$95; it was formerly \$90. The freight rate, at \$1.25 a hundred, with a minimum of 26,000 pounds, is about \$325 a car to New England. The Southern California Fruit Exchange for 2 years leased and operated its own cars in order to compete with the Earle Fruit Company, which had a car line, and with another company which was understood to have the benefit of the Armour line, and found the average cost of refrigeration to be \$46 a car on the \$75 rate and \$50 a car on the \$90 rate. Both President Hayes and President Ripley have said to Mr. Naftzger that they considered the refrigerator rates excessive and that steps would be taken to reduce them. Mr. Naftzger believes it to be the policy of the Santa Fé to put on its own refrigerator cars, of which it now owns a good many.

Mr. Naftzger is informed that up to last year the Santa Fé carried less than 10 per cent of the refrigerator cars west empty. They were held at various points for loads, and freight was transferred to them out of other cars. (956-958.)

Mr. Naftzger calculates that the freight on a box of lemons from Los Angeles to New York City is \$1.05 and the charge for refrigeration 30 cents. California lemons bring about \$2.50 per box of 300 in New York, or a little less than a cent apiece; late in the season they bring a little more than a cent apiece. If a box sells at \$2.70 the railroad gets half. Mr. Naftzger thinks it safe to say that the carriers get

at present approximately half the gross proceeds of California fruit sales of citrus fruits. The California fruit growers can not put their fruit in New York as cheaply as the Florida fruit growers can. (959.)

Refrigerator cars and cold-air funnels.—Mr. HALE does not think the cold-air funnel is a commercial success as yet. He once experimented with a car so equipped, but it was poorly handled at the farther end of the line. It was claimed that the road did not handle it properly because it had an interest in having the refrigerator cars maintained. Mr. Hale believes, however, that it will be possible to do away with the heavy refrigerator car and save the hauling of tons of ice. (398.)

B. Freight charges.—1. *The decline in freight rates.*—Mr. HOLMES says transportation has done great things for the farmer. The freight rate on wheat per bushel from Chicago to New York has decreased from 32½ cents to 12 cents since 1867. The all-rail rate on a bushel of corn from Chicago to New York was 36½ cents in 1858 and 11½ cents in 1897. The reduction in freight rates has given the farmers a world market, and has created foreign competitors and made American farmers competitors with one another. The Eastern farmer, when he found himself in competition with the West, had to diversify his agriculture. Mr. Holmes suggests that the gradual extension of the area of competition and of the number of competitors may have been an important cause of the falling prices, and have checked the further increase of prices of those products which have increased in price; but he adds that were it not for the present means of transportation the farmer would be living in the ways of the backwoods. (156.)

Dr. CROWELL says transportation rates on agricultural products have decreased during the past 50 years, largely through the competition of railroads for freight, with the effect of enlarging the markets for the farmer, but not greatly enhancing prices, because it has obliged him to compete with the surplus product of the world. The decline in rates has brought immense advantage to the consumer, but not much to the producer as such, though transportation facilities, including the mail, have enabled the farmer to avail himself of comforts and facilities for self-improvement and increased knowledge, probably the main factor in enabling him to maintain a high standard of living. (344.)

Mr. AGER, master of the Maryland State Grange, testifies that there has been quite a decrease in transportation rates, especially from the West to the East. This has affected the Maryland farmer adversely, so far as the sale of his products is concerned, by lowering prices as the trade from the West has increased, but it helps the dairy-men in buying bran and mill feed from the West. (115.)

Mr. GEORGE testifies that transportation rates have fallen materially as the equipment of the railroads has been improved. The producers, to some extent, get the benefits of the progress made by the railroads. (223.)

Mr. BRIGHAM believes that farmers pay every cent of transportation charges on agricultural products. The fluctuations in transportation charges are immediately felt in their full force in the price of the product to the farmer. Transportation rates have been largely decreased during the last 30 years, but the railways take advantage of large crops to raise their rates. The lowering of railway rates has deprived the farmers of the Middle States of the advantage of their location, especially since the through rates from the West are relatively much lower than the local rates. (23.)

Mr. STREVEN testifies that transportation rates have been very greatly reduced in Georgia since the organization of the State commission under whose control the railroads are operated. (916.)

2. *Cases of increased rates.*—Mr. KETCHUM, of Mercer County, N. J., says there has been very little change in transportation charges from that vicinity to New York and Philadelphia within recent years. The rates on some things, especially live stock, to New York were increased a few years ago. (136.)

Mr. MILLER, secretary of the Ohio State Board of Agriculture, says complaint of high transportation rates is general among the farmers of Ohio, and there has been much agitation for legislation.

Mr. Miller testifies that freight rates increased during the year preceding the date of his testimony (June, 1900), with the effect of reducing the value of the farmers' products. People who live 50 and 100 miles east of Toledo are obliged to pay freight to Toledo, and from Toledo to New York, in order to ship their products to the seaboard. A large part of the cereal products of Ohio is shipped west to Toledo before being started east, and the rate to the seaboard is greater from the eastern part of Ohio than from Toledo. Shippers in the interior points have trouble to get cars in the busy season. Mr. Miller is not in favor of making all the smaller stations through billing points, however. (613, 614, 616.)

Mr. NALL testifies that since 1895 there has been an increase of freight rates of from 10 to 30 per cent in Kentucky. The average increase would perhaps be 12½

per cent. In passenger rates there has been no change. The railroads justify the increase by the claim that commodities are worth more and should therefore bear a greater carrying charge. (813.)

3. *Excessive freight rates in the South.*—Mr. BARRETT considers the railway freight rates on cotton in the South excessive. It cost 90 cents to transport a 500-pound bale 32 miles from his home to Augusta. The rate from Augusta to Savannah is about \$1.30 per bale. The ocean freight to Liverpool, 3,000 miles, is from \$2 to \$2.50 per bale, so that the railway freight for a much shorter distance is almost as great. An official of the Georgia Railroad recently said that the company would be willing to reduce rates on cotton in round bales from competing points, but not from non-competing points. Sixty thousand pounds of cotton can be put into a car in round bales, and only 20,000 in square bales. (51, 52.)

Mr. PORTER, a cotton broker of Memphis, says there would be a great outlet for cotton in North and South Carolina if it were not for the prohibitive freight rates. The freight rates for uncompressed cotton are 59 cents a hundred to the Carolinas, and only 55½ cents to Lowell, and 50½ cents to New York. Mr. Porter has seen the time when he could send cotton from Memphis through Charlotte, N. C., to Liverpool for 42 cents, when it cost 59 cents to stop it in Charlotte. There is a physical division of the cotton business of the railroads which makes the rate to Carolina points noncompetitive. The cotton dealers have been endeavoring for some time to get the rate reduced, but without success, though for a little while they had it down to 42 cents. All they have ever asked is to have the Norfolk rate, which Mr. Porter thinks is 42 cents, apply to intermediate points. Mr. Porter thinks that if the Carolina planters would join in the effort, something might be accomplished. The reduced rate would be of benefit both to the raisers of cotton and to the planters in Carolina, and the railroads would have more cotton to haul. With the increased spinning capacity of the Carolina mills, the local supply of cotton is inadequate, and there is nothing to prevent building up business with them if a fair freight rate could be obtained. (481, 482, 485.)

Mr. MOSELEY, of Memphis, testifies that the river rate on cotton is a little cheaper than the rail rate, but the transportation lines stand by their agreements pretty well, and there is not much cutting of rates. (517, 518.)

Mr. PEEK, of Georgia, thinks the expense of transportation is one of the great drawbacks to the farmer. Mr. Peek lives 31 miles from Atlanta, and pays on freight to that city 15 cents a hundred for cotton and 4 cents a bushel for corn. A recent report of the Georgia Railroad Commission shows that the railroads have earned a dollar for every linear yard of road. (461.)

Mr. LOVEJOY says it is difficult to raise vegetables and fruits in Georgia for sale in Northern markets on account of the excessive freight rates. It costs much more, sometimes even twice as much, to ship goods from Georgia to New York as it does to ship them from New York back. This is probably due to the fact that there is no competition in taking goods north from any particular town, while there is competition out from the great cities. The rates to and from certain competing points in Georgia are much lower than elsewhere. Often it costs less to haul goods a greater distance on this account. Generally speaking, over the entire country there is discrimination in favor of large cities as against small towns. This practice is in a certain sense injurious to the cities as well as to the rest of the country, since it draws large numbers of laborers to work in the industries which are driven to the cities, and attracts others with the unwarranted hope of obtaining labor. When a depression comes there are great numbers of unemployed. Were the laborers scattered more throughout the country and employed in manufacturing in small places there would be much less difficulty from unemployment.

The two railways which reach the locality where Mr. Lovejoy lives, the Central and Southern systems, are under one management, although they claim not to be. There is some water competition, the city of Hawkinsville itself owning a line of small steamships, and this helps greatly in keeping rates reasonable.

The witness has nothing to suggest as a remedy for these discriminations beyond the present efforts of the Interstate Commerce Commission. (80-82.)

Dr. STUBBS, of Louisiana, believes that since the creation of the State Railroad Commission transportation rates have been regulated a little more satisfactorily. He believes the railroads have done everything the commission required, and the planters are not complaining about the rates. The great trouble about going into truck industries in the South is the high transportation charge to New York and Western markets, but that is a question of interstate commerce. (784.)

Mr. WEDDERBURN says the farmers of Virginia think the transportation rates are a little too high, but there is not as much complaint as in the past. Owing to the lack of organization, the farmers do not get together and talk over their grievances so

much. Moreover, there is a better feeling between the people of the State and the railroads than there was a decade ago. The railroads have better facilities and slightly more competition than formerly, and the managers are finding out that it is better not to antagonize the people so much; but there is still room for improvement. (632.)

Mr. CLOHAN says there is no board of railroad commissioners in West Virginia. The nearest approach to it is the Board of Public Works, which controls only the valuation of railroads for taxation. He favors having a board of railroad commissioners, with power to remedy unfairness in rates and accommodations. Frequent complaints of excessive rates have been made in the governor's messages and elsewhere. (604.)

4. **Rates on California fruit.**—Mr. NAFTZGER, president and general manager of the Southern California Fruit Exchange, testifies that the freight tariff is exactly the same now as it was in the infancy of the traffic, while the cost of operating has gone down all the time. This applies generally to the Pacific coast traffic, except such as is under the influence of water competition. Most of the California products are fruit, in which rail transportation is necessary. The cereals go by water to Liverpool. A considerable portion of the freight shipments to California have water competition, and pay about half the rate paid on fruit leaving the State. (964.)

Mr. Naftzger declares the existing freight rates too high. In the early history of the orange business in California they were, perhaps, not too high, as the prices were then high and the product comparatively limited. Now the citrus fruits amount to about 25,000 carloads and are steadily increasing, and they are much cheaper; consequently the margin between the selling price and the freight tariffs is diminishing, and, considering these conditions, the freight rate is excessive. The freight rate to mountain points, such as Denver, Pueblo, Cheyenne, Salt Lake, and Montana points, is \$1.124 a hundred. For all points farther east the rate is \$1.25 a hundred everywhere. If the Southern California Fruit Exchange had control of the entire product for distribution, a graduated rate on a mileage basis would be preferred. The cheaper class of fruit could be put into the cheaper territory of the West and Northwest, and the continual forwarding to other markets would be eliminated. About 5 per cent of the California fruit is sold on the Pacific coast; another 5 per cent is sold in the mountain territory; about 18 per cent goes to Missouri River points; Chicago and other Mississippi River territory take about 17 per cent; the trunk-line territory about 15 per cent; Buffalo and the East about 38 per cent, and the rest is scattered through the South. (961, 962.)

Mr. Naftzger says the Southern California Fruit Exchange loads a car with its minimum load of 26,000 pounds and pays \$1.25 a hundred. There is a "postage-stamp" rate on citrus fruits—that is, the same rate prevails to all points east of the mountains. (947.)

Mr. Naftzger says most of the other classes of freight are hauled at a much lower rate than fruit, and some of them on equally good time. The railroads claim that fruit is very expensive to transport, because it has to be hauled on expedited trains. (956.)

It seems unreasonable to the people on the Pacific coast for the carriers to say that in competition with water rates they can haul goods from New York or Chicago to the Pacific coast for 50 cents a hundred, but that they can not afford to haul California products for less than \$1.25 to \$1.60 a hundred. If the water competition makes the business unprofitable the carriers ought to let it go by water. A very large percentage of the cost of operating is in the handling of the freight itself; but the carriers never handle the fruit. Mr. Naftzger concedes that one of the reasons for the high rates is that the cost of hauling the transcontinental or mountain freight is about twice the cost on the prairie roads. (962.)

5. **Recent freight reductions in the Northwest.**—Mr. HANLEY, business agent of the National Farmers' Alliance and Industrial Union, says that the association had a bill to reduce freight rates in general 20 per cent, and was going to make a campaign issue of it. As a compromise Mr. Hill, of the Great Northern, reduced the rates on grain about 14 per cent, and the other roads had to follow the reduction. The reduction amounted to about \$1,100,000 on the Great Northern and about \$3,400,000 on the other roads. Mr. Hanley believes that the rates are still too high. (280, 281.)

Mr. MORAN says that in 1898 associations of farmers secured a reduction of freight rates in the wheat belt of the Northwest amounting to about 14 per cent on wheat. They asked for 20 per cent, and had a committee nominated to present the measure in the State legislature, but this became unnecessary, as one of the roads voluntarily reduced the rates on grain. The president of this railway said he proposed to donate \$1,098,000 to the farmers by reducing rates on grain 1 cent per 100 pounds the first

100 miles, 2 cents for the second 100 miles, 3 cents for the third 100 miles, and 4 cents for the fourth 100 miles from the terminal market, etc., giving the farmer farthest away from the terminal market 4 times as much reduction as those near by, thus helping to equalize freights. The reduction which this road inaugurated on grain rates from the wheat fields of the Northwest to terminal markets of Duluth and Minneapolis compelled other roads to meet the reduced rates, and the reduction on that season's crop was computed at \$3,400,000. (712.)

Mr. JUMPER testifies that in 1898 the freight from Aberdeen to Minneapolis was reduced 2 cents, from 12 to 10 cents a bushel. (737.)

Mr. PROM testifies that the freight rate on the Great Northern Railroad was voluntarily reduced about 2 cents a 100 pounds throughout North Dakota since 1897. (795.)

Mr. BUDGE thinks that the rate from Grand Forks to Duluth is 14 cents a 100 pounds, or 8.4 cents a bushel. Formerly the rate was 17, 18, or 20 cents. The decline has added something to the value of farmer's crop. (853.)

Mr. GREELEY, of South Dakota, says that transportation rates have sometimes fluctuated a little in recent years, but the tendency has been downward. Much time has also been gained in stock shipments. Stock is sent to Eastern markets with one-half the shrinkage formerly experienced, and at lower rates. (938.)

Mr. PRATT, of Aberdeen, S. Dak., says freight rates have fallen in the past 10 years, and every time the railroad reduces the rate the reduction goes into the producers' hands. The lower the rate the more the farmer gets for his products. (727.)

6. Farmers not benefited by reductions of freight. (See also XII D 1, Powers, p. cxcxii.)—Mr. MORAN declares the general belief that any reduction in freight rates on grain will go to the producer to be entirely erroneous, so far as it applies to wheat. The reduction secured in 1898 did not increase the price 1 cent the day the rates went into effect. The farmers have therefore concluded that the reduction of freight rates on grain crops is of no practical benefit to them. The reduction which was intended for the producer in fact went to the consumer, reducing the price to the farmers of the entire world, while the railroads lost the amount of the reduction. The various wheat countries of the world bring all the surplus wheat of the world to Liverpool, and the buyer in that market makes the price. A man sending wheat to Liverpool who has a larger margin than he ought to have may, by reason of that margin, make his bid lower than the other sellers, but his competitors will immediately "drop" to get the order. Even if the entire freight charge were wiped out, it would not, in the long run, add a penny to the price received by the farmer, because sellers in the Liverpool market would offer wheat lower. Other countries would reduce their price level, even if they had to sell their product below cost, because there is a surplus, and it must be marketed. Mr. Moran declares it to be the opinion of the Grain Growers' Association that the abolition of the freight rate would work no advantage to the producer. As long as Liverpool is the market of the world, he says, and all the agricultural nations are competitors in that market, Liverpool will always be able to dictate the price at which the products must be sold. (712, 713.)

Mr. Moran says the farmer pays the freight on wheat, the farm price of the wheat being reduced by the amount of the freight; but reductions in freight rates benefit the consumer, not the producer. (714, 715.)

Mr. Moran testifies that the 14 per cent reduction given by the Great Northern Railroad went into effect July 16, 1898. Mr. Moran watched the price of wheat to see if the change made any difference, and to his astonishment found that there was no difference whatever. He made comparisons with the price paid the day before the reduction took effect, and also with the price a week later and a week earlier; he also learned as far as he could through the public press the state of the foreign market and the price at other stations, without finding any difference. The reduction of 14 per cent did not amount to quite 2 cents a bushel. Mr. Moran admits that if the freight rate to Minneapolis and St. Paul were cut in two the farmers might for a very short time receive some small benefit. (718.)

Mr. Moran testifies that the farmers connected with the National Grain Growers' Cooperative Association generally believe that a reduction of freight rates would not benefit them. Outside of that organization they have not generally come to that conclusion, but still believe that the benefit of a reduction of freight goes to the farmer. Mr. Hill, at the time he made the reduction, firmly believed that the difference would go into the pockets of the farmer, but he changed his views, and now believes that the farmer does not get the benefit of a reduction on wheat. (718.)

Mr. Moran believes that when the freight was reduced the country buyers or shippers understood that they received a temporary benefit. (722^c)

C. Railroad combinations.—1. Rate agreements.—Mr. RICHARDS is satisfied that there is just as much of a railroad pool as there ever was. The Traffic Associa-

tion is nothing but a pool, which has been doing business on the same lines as in the past; he has no reason to believe that its methods have been materially changed, though it may be a little more cautious. (209, 210.)

Mr. CLOHAN says the farmers of West Virginia sell their grain largely at Baltimore, and the rate is about the same as from Chicago. There are two roads, but apparently there is a combination between them to maintain rates. (603.)

Mr. PORTER, a cotton broker of Memphis, refers to a cotton committee representing the various railroads, which, he understands, has a secretary paid by the different railroads, who promulgates all the cotton rates. (484.)

Mr. NORRIS says New York farmers are not so materially affected by combinations of railroads and elevator men as those in some Western States, because there is such competition between different lines of road, and the Erie canal is a balance wheel. The railroads can not pinch the farmers as hard as they do out West, except between noncompetitive points. (331.)

2. *Pooling of cotton.*—Mr. GAGE testifies that the different railroads carrying cotton and cotton goods from Memphis to New York, Boston, and other ports have a pooling contract which he thinks has been very rigidly adhered to. (495.)

Mr. PORTER, of Memphis, thinks a better freight rate could be obtained if the physical division of freight among the railroads could be done away with. When the Southern, for example, has as much freight as it is allowed by the arrangement, it has to turn the remaining cotton over to some other road. Each road is allowed its percentage on the cotton freight, whether it hauls it or not. There was a lawsuit about this in 1899, but the Supreme Court of Tennessee decided against those who attacked the pool. (484.)

Mr. MOSELEY, a cotton dealer of Memphis, testifies that a great deal of business has been lost to Memphis shippers because certain large spinning establishments in the East want their cotton shipped over certain lines, and the cotton shippers in Memphis can not choose their routes on account of the physical division of cotton among the railroads. Until a few years ago there were fast freight lines whose agents made export rates; but they can not do so any more, because initial lines dictate the road that cotton must go over, and have thus cut off the competition which enabled the shippers to get very much better rates. Mr. Moseley thinks pooling is opposed to the best interests of Memphis. (517.)

3. *The California fruit pool.*—Mr. NAFTZGER testifies that the Southern California Fruit Exchange at one period got a railroad rebate, as did everyone else, but now gets none whatever. There was a time in the history of the California business when almost every commodity had its special privilege or rebate in some form. Under the existing order of things the rate is firm by reason of the arrangement between the carriers. The two initial railroads operating in California—the Atchison, Topeka and Santa Fe and the Southern Pacific—divide the business between themselves and parcel it out to their connections. Formerly the flexible rates were usually made or the rebate obtained through a private car line, several of which were operating. Speculators whose sole hope of reward was in the rebate dipped into the traffic, contracting with the producers to handle the crop. The producers were no better off for the rebate, and usually the crop was poorly handled. The system was extremely demoralizing to the business, putting it into the hands of those who were not prepared to handle it properly. The establishment of a steady rate eliminated these so-called pirates. While Mr. Naftzger understands that an association as large as the Southern California Fruit Exchange is very likely to get special benefits from shifting rates, he believes the steady rate desirable in the interests of the industry, as well as of good morals. (946, 947.)

Mr. Naftzger says the initial carriers have control of the routing of the freight to its destination, and give it out to their connections to suit themselves, merely giving the shipper the privilege of determining what terminal he desires and of diverting his shipments in transit; that is, a car shipped to Kansas City may be diverted to Chicago, to Buffalo, and to Boston, the same rate applying to Boston that applied to Kansas City. (961.)

Mr. Naftzger's reasons for believing that there is an understanding between the two railroads are: In entering into contracts with the refrigerator lines the two companies contract for precisely the same amount of equipment. They have repeatedly refused to permit fruit to be loaded on one line and forwarded on the other line, because the second line was already ahead in the shipments. They have repeatedly asked the shippers to even up the shipments between them. They have refused to allow fruit to be hauled from the vicinity of one road and loaded and shipped out on the other line; they have insisted in such cases upon billing the car over the road near whose line the fruit was grown. (963.)

Mr. Naftzger testifies that in a case pending before the Interstate Commerce Commission complaint was made against both the initial carriers in California for discrimination in favor of one shipper over others, this one shipper having under his ownership and control a line of refrigerator cars, not only for his own benefit, but into which the Fruit Exchange was forced to put its shipments, which were thus made under the notice and, to a certain extent, under the surveillance of a competitor in business. Complaint was also made against the refrigerator rates and against the custom of the carriers in taking the routing of the business into their own hands. The whole private-car system was complained against, the contention being that the carriers had no right to farm out the business to other corporations or individuals, and that it was their duty to furnish equipment under their own control. The refrigerator rate is believed to be excessive because of this combination. Formerly some reductions from the published rates could ordinarily be secured, but that can not now be done. Since the agreement was entered into between the initial carriers and the car lines the freight rates and the refrigerator rates have remained firm and arbitrary. Complaint was also made to the commission of the increase of the minimum carload weight, which for citrus fruit was increased from 20,000 to 21,000, then to 24,000, and finally to 26,000 pounds. This has worked a hardship to the shippers, because many of the cars were unsuitable for carrying so heavy a load, causing a great deal of loss by decay, and also because many Western markets that would take a small carload could not take a large one. Thus wholesale markets were converted into retail and jobbing markets, and many small towns were forced to get their supplies through other cities secondhand instead of getting them direct in car lots. Prices were thus raised and the consumption and demand limited. (961.)

D. Discriminations.—1. **Between localities and classes of freight.**—The farmers of New Jersey, Mr. DYE says, complain greatly that relatively lower rates of transportation for longer distances have greatly injured them by enabling fruit, vegetables, milk, etc., to reach New York markets at exceedingly low prices. There are also discriminations in classification, especially on the basis of relative perishability of freight. (96.)

Mr. BRIGHAM says the grain dealers get advantages over the farmers in the matter of rates; the rates from Western farms to Chicago are much higher than those paid by the dealers from Chicago to the East. (23.)

Mr. NORRIS, master of the New York State Grange, says the man who has access to the Chicago market is better off than the man living in western New York. A man who has to depend upon local transportation between noncompetitive points can not get the fair rates that exist between competitive points. (328.)

Mr. CLOHAN says the Baltimore shipper puts his fruit into the Wheeling market at 25 cents, while fruit growers 100 miles nearer have to pay 50 cents. (604.)

Mr. JUMPER, of Aberdeen, S. Dak., says the farmers complain that the freight rates between points in South Dakota and Minneapolis are too high in proportion to the rates for greater distances. The rate from Aberdeen to Minneapolis is 17 cents a hundred, or 10.2 cents a bushel; to Duluth it is 20 cents a hundred, or 12 cents a bushel; to Chicago it is 27 cents a hundred, or 16.2 cents a bushel. The distance from Aberdeen to Minneapolis is 280 miles, and from Aberdeen to Chicago 700 miles. The rate for the first 300 miles is 10.2 cents and for the last 400 miles 6 cents. (739, 740.)

Mr. NALL testifies that complaints of discrimination are numerous in Kentucky. (813.)

2. Special rates and rebates. (See also XIII C 3, p. cccv; XIV A 15, p. cccxxiii.)—Mr. RICHARDS says the stability of a rate is more important than the rate itself. Of two dealers buying wheat at the same time and at the same prices, one can sell more cheaply than the other because of discriminations. Mr. Richards thinks discrimination is practiced more than formerly from the fact that it has driven men out of business. Men who made money on the Chicago Board of Trade a few years ago are practically doing nothing. (206, 210, 211.)

Mr. S. H. GREELEY says the railroad managers are able to dictate the freight rates paid by an individual and by his competitors, and are thus able to make or unmake almost any business man or almost any community. (231.)

Dr. CROWELL has no doubt that discriminating rates exist. Corresponding to the published standard rates, which the small shipper has to pay, are secret special rates known only to a few persons. They are made by contract with the company for a period of months. Dr. Crowell is informed by a railway employee that it is a common thing for an official to have by his side a stack of special rates as high as a table.

The differential between Chicago and New York on the seaboard lines is practically nonoperative at present, because they have more freight than they can well handle; but when they have less freight than they can conveniently handle, the differential will be enforced, and the rate cutting will go on. (345, 346.)

Dr. Crowell considers it impossible to deal with discrimination from the standpoint of the individual Commonwealth. Pennsylvania made a strong effort to prevent discrimination, but it practically amounted to nothing, because the larger part of the commerce was interstate. (337.)

Mr. NORRIS, master of the New York State Grange, thinks there have been large rebates made to large shippers in New York State, and is inclined to think that large shippers are entitled to discounts. (328.)

Mr. GEORGE, of Chicago, says railroad rates are not always reasonable under present laws, and that large shippers are favored while the class which needs favors is discriminated against. The railway companies cater to the elevator men and grain buyers, because it is less trouble to deal with them. The farmer who has a carload of grain to ship may have to wait a month or two before he can get a car, and becomes discouraged and sells out for whatever he can get; but a railroad company will see that a buyer who applies for 10 cars gets them promptly. In many cases if the buyer finds that the farmer wants to ship grain he will order a few more cars than he wants to use, more than the company is willing to furnish at that point, and the farmer, needing money, gets discouraged and sells out for what he can get. (225.)

Mr. WILSON, master of the Illinois State Grange, thinks big shippers have a little advantage, though he has never been able to get absolute proof. (252.)

Mr. WEDDERBURN knows of a man who contracted with a railroad to have 100 barrels of flour delivered at a certain price, but packed about 500 barrels into the car. The railroads make contracts with large shippers for a smaller amount, and allow the shipper to exceed the shipment, without any supervision. (633.)

Mr. MOSSELEY, a cotton dealer of Memphis, says a great many of the cotton people think the railroads grant special favors to some shippers by rebating all the local rate to Memphis when the cotton is reshipped, thus giving an unfair advantage to the exporter. (516.)

E. The interstate-commerce law and proposed reforms.—1. Criticisms of the existing law.—Mr. RICHARDS, a grain merchant of Chicago, understands that the interstate-commerce law was passed for the purpose of preventing discrimination, but in passing it Congress was led to apply certain remedies which the courts have declared unconstitutional. A man can not be compelled to testify against himself. Then they sought to amend the law by relieving the witness of criminality. Discrimination in the long and short haul has been another perplexing question. Mr. Richards says the law has been inoculated with vicious provisions which destroy its efficiency as a protective measure. It neither confers the requisite powers upon the commissioners, nor reaches the foundation of the wrongs it was intended to correct. (207, 208.)

Mr. Richards has never regarded the interstate-commerce law as amounting to anything, except as a kind of club held over the railroad company if it will not give a man a pass. Mr. Richards says the law was hailed with a good deal of pleasure by the railroads because it simplified their business. They thought it would be a great deal better to give a rebate to one man than to 100 or 500. (204, 206.)

Mr. GEORGE says the interstate-commerce law seems to be inoperative in a good many ways; not much progress has been made under it. It is a compromise measure; there were three or four bills in Congress and a compromise was necessary. A good many people have lost confidence and say that it is worse than no measure at all; but Mr. George thinks it a step in the right direction. (226.)

Dr. SCRIBBS says there is considerable complaint in the South that the Interstate Commerce Commission is not doing what it was expected to do. It was thought that it would regulate rates so as to give the farmer an opportunity of putting his products in the markets of the world on an equality with the rest of the world. Complaints arise from time to time in Louisiana that such and such a place is getting rates that Louisiana can not get. (784.)

Mr. HAMILTON thinks the general feeling in Pennsylvania is that the interstate-commerce law has been a very valuable aid in preventing freight discriminations. (373.)

2. Increase of the Interstate Commerce Commission's powers advocated.—Mr. JONES believes that the question of transportation is of the greatest importance to all industrial interests. Railways, like all others who have the power, are likely to be grasping and extortionate. Legislation, therefore, is necessary. The power of the Interstate Commerce Commission should be increased. (31.)

Mr. BRIGHAM would give the Interstate Commerce Commission more power, so that it could remedy the wrongs it finds. (27.)

Mr. MILLER suggests that the Interstate Commerce Commission's powers should be enlarged and that it should have better facilities for enforcing its orders, as already recommended by the Industrial Commission. (See vol. 1, pp. 6, 7.) He thinks this

CCCVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

view is pretty generally entertained by the farmers. There is a pretty general feeling in Ohio that there should be some State legislation in the matter of passenger travel, but that the National Government should control the transportation of commodities. (618, 619.)

Mr. RICHARDS says the commission should be given judicial or police powers and supervisory power to control every detail connected with transportation, including weighing, storage, inspection, and transfers from one line to another. Mr. Richards thinks the Interstate Commerce Commission could be clothed with power to do anything that would facilitate and promote interstate commerce. He does not believe, however, that the rate-making power should be given the commission. (206, 207, 211.)

Mr. Richards proposes amendments to the interstate-commerce law empowering the commission to supervise the inspection, storage, weighing, and transfer of all interstate shipments of grain and seeds, and to make and enforce rules and regulations to prevent improper inspection, grading, or weighing, mixing of different grades, or separating different qualities of the same grade, and giving the commission the complete jurisdiction of a trial court, appeal to lie to the court of appeals, whose decisions should be final except on constitutional questions; also requiring bills of lading to state the actual net weight of each carload of grain or seeds, claims for shortage to be adjudicated by the commission on that basis, and prohibiting the storage of grain in any elevator or other place of storage the owner, manager, or agent of which deals in grain on his own account without the written permission of the owner of the grain so stored. (218, 219.)

Mr. Richards would have one member of the Interstate Commerce Commission an agriculturist, another representing the manufacturers, another representing the commercial and merchandising interests, and one an attorney. (220.)

Mr. NAFTZGER thinks the Interstate Commerce Commission or some proper tribunal should have power to determine what are reasonable rates and to classify rates. At present, where the carriers are forbidden to increase the rate without the consent of the Interstate Commerce Commission they accomplish the same result by changing the classification. The order of the commission ought to go into effect as soon as made, subject to the right of appeal. Mr. Naftzger thinks it is not extremely difficult to ascertain what is a reasonable rate. (962, 963.)

Mr. WILSON says there is a general demand in Illinois for an increase of the powers of the Interstate Commerce Commission. (254.)

Mr. PORTER, a cotton broker, believes in giving the Interstate Commerce Commission greater powers. (484.)

Mr. GEORGE is in favor of giving the commission more power. (226.)

Mr. WEDDERBURN suggests, as a remedy for railroad discriminations, giving the Interstate Commerce Commission authority to enforce its rules and regulations. (633.)

3. Prevention of special rates and rebates.—Mr. RICHARDS says all rates should be uniform and based upon single carloads as the unit. Discriminations, special rates, and rebates should be absolutely prohibited. The small shipper should be protected as much as the big one. (206, 210.)

Mr. MORAN, president of the National Grain Growers' Cooperative Association, desires a rigid execution of the law preventing railroads from granting rebates to specially favored shippers. (719, 720.)

4. Legalisation of pooling.—Mr. GEORGE advocates the legalization of pooling under the strict surveillance of the Government, so as to give the people the benefit of whatever advantage the railroads may derive from pooling. Competition, he says, is wasteful and leads to discrimination. (224.)

Mr. RICHARDS, a Chicago grain merchant, thinks it would hardly pay to legalize pooling, but it would depend upon how it was legalized. If the laws of trade could be carried out, the question of rates would regulate itself under competition. If a railroad can not get what it considers its share of the business at the legal rates, it will cut rates, no matter how strong the agreements are. (210.)

Mr. GREELEY, a Chicago commission merchant, does not believe the permission of pooling would prevent cut rates and special warehouse facilities. (231, 232.)

Mr. WILSON, master of the Illinois State Grange, does not see that any possible benefit can come to the producer from the permission of pooling, and is opposed to it on principle. He believes in open competition among railroads as in everything else. (254.)

Mr. BARRETT believes that combinations among railways to prevent legitimate competition should be prohibited. He speaks especially of the consolidation of parallel lines, as in the case of the South Carolina and Georgia and the Charlotte and Columbia roads, and in the case of the Central Railroad and the Georgia Railroad.

The constitution of Georgia prohibits such combinations, but the State officers do not enforce it. (55.)

5. Government ownership.—Mr. WILSON, master of the Illinois State Grange, thinks the Government should entirely control the railroads, and if it can not control them he favors Government ownership. (254.)

Mr. S. H. GREELEY, a commission merchant of Chicago, emphasizes the importance of stable and uniform freight rates, and says they will never be secured until the Government owns the railroads, under a satisfactory system of civil service. The idea of attempting such a gigantic undertaking without such a system of civil service seems to him folly. (231, 232.)

F. Wagon roads.—1. **Poor character of American country roads.**—Professor BAILEY, of Cornell University, says that American country roads are very poor, partly because of the great extent of the country and the large holdings, and partly because in many regions the railroads developed before the wagon roads, and the need of road improvement has therefore been less imperative. In many great regions road material is scarce and expensive. Poor roads add to the unattractiveness of farm life, and are therefore socially as well as economically important. They can not, however, be considered as an underlying cause of any agricultural decline. The agitation for good roads might easily be carried too far, for the building of roads might often entail more expense than the adjoining property is worth. (1012.)

2. Cost of transportation.—Mr. DODGE, director of public road inquiries, United States Department of Agriculture, has investigated the cost of transportation on common roads by animal power, and found the average cost per ton per mile to be about 25 cents, as compared with one-half of 1 cent by steam power and 1 mill by steamship on the Great Lakes. In many instances where there were partial loads and very bad roads the cost would be 50 cents a ton-mile. The average cost over the best improved roads is between 10 and 15 cents in this country, though, according to consular reports, it goes as low as 8 cents in European countries.

Mr. Dodge says that General Stone, his predecessor in office, on the basis of inquiries in 1,200 different counties, estimated the cost of transportation at 25 cents a ton-mile, and the Maryland commission has estimated the cost at 26 cents. The cost in Mexico has also been estimated at 26 cents. (690, 691, 700.)

Mr. Dodge considers the cost of moving materials over highways unnecessarily high. He says there has not been much reduction in the cost during a long period of time, but estimates that four-fifths of the present cost can be saved. The cost would then be 10 times the average cost of transportation on steam cars. (693.)

Mr. SPEAR, of Vermont, says the cost of transportation has been reduced in the past 40 years by the railroads and by improved highways. (408.)

3. Importance of road improvement.—Mr. HAMILTON believes the country would be greatly benefited by good roads. The building of a good road out to a farm brings it nearer the place of business and enables the farmer to haul double the load he did before, and saves time to that extent. The labor and time of the farmer are very much more valuable than formerly. (370.)

Mr. DODGE declares that population, like everything else, moves along the line of least resistance, and good roads form lines of less resistance than poor roads; hence, where the better roads are there will be the greater numbers of people and the greater wealth. Better modes of transportation not only increase the power of production and the value of land, but have a more powerful influence on the location of the people than anything else. (703.)

Mr. Dodge has no doubt that great fortunes result largely from taking advantage of cheap transportation. The community which lacks cheap transportation never has any rich people. Those parts of the country which have no means of transportation but animal power are universally poor. The value of land is estimated by the distance from cheap transportation. Mr. Dodge believes it is the duty of government—national, State, and local—to turn its attention to road improvement, not only because of the added value, but because it tends to place people more nearly upon an equality as to the value of their property, the profits of their industry, and the rewards of their labor. (698.)

Mr. Dodge says that when the steam engine was first developed as a locomotive the intention was to move ordinary small vehicles, only about 3 or 4 or perhaps 6 in a train; but the engine was developed so as to draw heavier burdens than was expected, and the size and speed of the vehicles were increased. The running of these large cars so cheaply and so fast diverted attention from the smaller vehicles and from the improvement of the highways; but there is still a necessity for the small vehicle to serve people locally. The large vehicle is not satisfactory for the short haul, and there is to-day no cheap means of transportation for distances of from 5 to 10 or 15 miles. The high rates for short hauls, with the loading, unloading, and hauling at

each end, makes the cost about equal to that of using animal power for the entire distance. The problem is still unsolved, but the prospect of results beneficial to all classes is much greater than ever before. (699.)

Mr. JONES, master of the National Grange, considers the building of good country roads of very great importance. Every dollar wisely invested in this way would return 200 per cent. The chief advantage to the farmer would be the possibility of taking his goods to market at any time, thus preventing the fluctuations in prices due to the stopping of such transportation. Good roads would prevent the necessity of disposing of products immediately and of storing them in great elevators. The knowledge of buyers that so much grain is on store in elevators tends to depress prices, while storage in farmers' granaries would not have so great an effect. Moreover the cost of insuring grain on the farm is less than in the city elevators. (39.)

Mr. KETCHUM, of New Jersey, thinks good roads will be of no great benefit except to the farmers adjacent to the large cities, especially dairymen who go to town every day. (136.)

Professor DAVENPORT says there is a good deal of wrong figuring as to the economy of good roads, and a great danger of magnifying their financial necessity. In any agricultural section that is producing crops extensively the roads are comparatively good a large part of the year. In Illinois it is possible to send heavy loads over the roads a good share of the season, and there is an immense amount of unused horse labor on the farms. Professor Davenport, however, mentions other arguments for good roads which he considers convincing: their convenience, uplifting influence, and advantage in making country life happier. (273.)

4. Road improvement in various States.—*Massachusetts.*—Mr. STOCKWELL says that the roads of Massachusetts are good in comparison with other States. Under the Massachusetts law the Highway Commission builds a mile of road here and there in the towns, free or nearly free, as an incentive to the towns. The plan is eventually to bring these lines into communication, making a continuous road from the eastern to the western boundary of the State. The country towns can hardly imitate such good pieces of road, but they are having a good effect in increasing the number of good roads. Mr. Stockwell regards the roads as an index of the character and civilization of the people. He thinks the Massachusetts roads and roadsides are becoming increasingly comfortable and attractive. There is a forestry association which works in harmony with the Board of Agriculture in this matter. The State appropriations for State roads, including bridges and culverts, have amounted to more than \$3,000,000. (896.)

New Jersey.—Mr. DYE enumerates several systems of road building in operation in New Jersey—the old township system, special county systems in particular counties, and the State-aid system. The latter was established as the result of efforts by the State Board of Agriculture and of State road conventions held during three successive years. The appropriation by the State has increased from \$75,000 per year to \$150,000, and the system has become more popular with the people. Under the law, if two-thirds of the property owners living along any road petition for an improved road it is built under the supervision of the State, one-third of the cost being met by the property owners benefited, one-third by the county, and one-third by the State. The road then becomes a county road maintained at county expense. The original act required that such roads be constructed of macadam or telford, but late amendments allow them to be built of gravel, oyster shells, or bog ore. The cost per square yard varies from 20 cents to 70 cents.

Improved roads are of special advantage to those who can haul their own products, especially vegetables, to the market over them. They are of less advantage to other farmers. (94-97.)

Pennsylvania.—Mr. HAMILTON says the system of road construction in Pennsylvania is very imperfect. "It is the old method in most of the districts of working out or loafing out the tax." It is in the hands of inefficient men, because a business man or a man of any considerable occupation can not afford to be a road supervisor, and a man is selected for that office because he is unable to do anything else. It is often a polite way of keeping him off the township. He gets \$200, \$250, or \$300, and wants to keep the position, so he does not urge those who are called out to work under him to do more than is absolutely necessary. Thus he secures reelection year after year, and after 20 years of such service the roads are no better than when he began. There are about 100,000 miles of roads in Pennsylvania, outside of boroughs and cities, which cost about \$4,000,000 a year, or at the rate of \$40 a mile, and 80 or 90 per cent of them are very little better than they were many years ago. Where gentlemen have put up country residences and taken an interest in road improvement, notably about Philadelphia, good roads have been built. Mr. Hamilton thinks it perfectly practicable, with business energy, to put the roads into good condition with the taxes now levied. In most districts there is an abundance of good material. (369.)

Ohio.—Mr. MILLER testifies that the roads through a very considerable part of Ohio have been improved under the general turnpike and the 1 and 2 mile assessment laws. The matter is taken by petition before the commissioners of the county or counties over which the improvement is to extend, and if the prayer is granted by the commissioners the improvement is made and the benefits are assessed within 1 or 2 miles. In many cases the cities at the termini of the improvement are assessed for a considerable share of the expense. The assessments are finally passed upon by the county commissioners. The counties which originally had the most impassable roads now have the best roads in the State, usually of broken stone or gravel, for in some counties, where the roads are passable in a state of nature, improvements have not been made. The expense of bridges and culverts, when exceeding \$50, is borne by the counties, anything less than \$50 by the townships, unless in case of a road improvement. The bridges are sometimes added to the assessment, but not as a rule. Ordinarily the land benefited pays for the grading and macadam or graveling of the road, while the county or township pays for the bridges and culverts. It is unlawful to haul more than 2,500 pounds on a wagon of narrow tread over an improved road. This law has had the effect of multiplying broad-tread wagons very greatly, and many farmers now have no narrow-tread wagons. (608, 609.)

Michigan.—Mr. SMITH says the roads in Michigan are universally bad in the fall. He has watched loads of sugar beets at the Alma factory which did not average 2 tons. If a man has to haul beets 3 miles and makes only 1 trip a day, it takes nearly 5 days to deliver an acre of beets. On the good stone roads about Bay City Mr. Smith has seen 3-horse teams haul from 3 to 5 tons of beets at a load, and the cost of delivering is thus materially reduced. Good roads are needed and are demanded by the towns and villages where beets are grown. (576, 578.)

Illinois.—Mr. BURKE testifies that a bill was introduced in the Illinois State legislature at the session of 1899 providing for road improvements, 50 per cent of the cost to be paid by the State, 35 per cent by the counties, and 15 per cent by the abutting farms. The farmers defeated the measure on the ground that the 50 per cent and 35 per cent would largely come out of their pockets also, showing that they realize how justly they are treated in the matter of taxation. (197.)

Minnesota.—Mr. M. F. GREELEY testifies that in some parts of Minnesota the roads are so poor as to detract from the value of the adjoining lands. There is a disposition to improve the roads, but every district is left to one man's ideas, which sometimes are very crude. Enough money is spent on the roads, but there should be a more intelligent and general supervision. (938.)

North and South Dakota.—Mr. GREELEY testifies that the roads are excellent in North and South Dakota regardless of the work done on them, because the dry climate and soil make good roadbeds. (938.)

Mr. BRIDGE says the roads in North Dakota are bad only in the spring for about two or three weeks. In the fall they are hard and like paved roads. There is very little material in the State for making macadam roads. Bridges of any considerable size are built by the counties, and the townships put in the culverts. The grading is done by the farmers in payment of the road tax. There is an improvement in the roads from year to year. (853.)

Mr. PROM says the condition of the roads in North Dakota has not been very good, but is improving. The clay of the ground is the only material for road making, but if the roadbed is properly built it makes a very good road, dry in summer and frozen hard in winter. Interest has recently been awakened in the good-roads question, and attention is always called to it in the institute meetings. (794.)

Maryland.—Mr. AGER, master of the Maryland State Grange, says that the county commissioners of Maryland appoint road supervisors, generally appointing men of their own party as compensation for political work. Prince George County is divided into 14 road districts or precincts, with 3 commissioners for each, whose duty it is to go over the roads and report as to the amount of money they need to have expended on them. In Mr. Ager's experience as a road commissioner the reports were pigeon-holed nine times out of ten. Mr. Ager thinks Gen. Roy Stone was about right in saying that \$600,000 a year had been spent in Maryland for the improvement of roads which were never improved. The roads are no better than they were 20 years ago, while if the money were judiciously used there might be good macadamized roads all over the State. Citizens are not required to work the roads. Funds for road building are furnished by the county, with no aid from the State. (112.)

Kentucky.—Mr. NALL, of Kentucky, says that in the blue grass section, which is a hilly or rolling country, there are excellent roads of broken limestone rock, formerly toll roads but now nearly all free. There is not much gravel in the State, but there are fine deposits near Paducah. In the lower part of the State, where the material for pikes is lacking, the roads are bad—just ordinary dirt roads; but some little improvement has begun there. Mr. Nall looks forward to better roads and better bridges.

He brings up the road question in all his institute work, making the farmers think about the question, and they are changing the system of keeping up the roads. Mr. Nall's opinion is that roads kept up by taxation and road supervisors are better than those maintained by the "call out the hands" system. Where a county has a road commissioner they are making better roads, because the commissioner studies the subject and works to improve one bad place permanently, and next year goes to another one. Under the old system the residents, when called out, "would scratch around a little and they would never come back again." The whole system was bad. The funds for improving the roads are raised by a county tax, but Mr. Nall believes that in most of the counties the magisterial district in which the tax is paid controls the fund, so that it can be expended only in that district. The law differs in different counties, however. (813.)

North Carolina.—Mr. WHITE testifies that the best system of roads North Carolina ever had was under a recent law imposing a road tax to be kept separate for each township. Overseers were required to keep up the roads with so much money, hiring labor where they pleased. (431.)

Mr. HUTCHISON, chairman of the board of trustees of Charlotte Township, Mecklenburg County, N. C., says that some 15 or 20 counties in North Carolina, out of a total of about 90, have adopted a system of road building. Mecklenburg County started the system some 12 years ago. For a few years road building was at a standstill, but during the last 8 years it has increased each year. (1047, 1048.)

It has been the policy of Mecklenburg County to build out from Charlotte on the main roads, in rotation, a mile or more of macadam road at a time. This was thought to be the best system, as, through it, everyone coming to town would have the use of a mile or so of good road. This plan has been pursued until there are 90 miles of macadam road divided among 13 roads, and the work of building is going on at the rate of 8 to 10 miles per annum. (1039.)

Mr. HUTCHISON says Charlotte Township recently secured the enactment by the legislature of a law establishing standard widths of tires, and imposing a license charge of from \$1.50 to \$5 on all wagons in the township with tires less than the standard width. (1040.)

Mr. HUTCHISON says that since the county of Mecklenburg has been building macadamized roads, farming lands on macadamized roads within 2 to 10 miles of town have increased from 50 to 100 per cent in value, the value of suburban property having increased much more than has the value of city property. Rural mail delivery has been made possible by the building of good roads. Where 4-horse teams used to be the rule they are now the exception. Formerly half a cord of wood would be hauled with 4 horses. Now a cord and a quarter is hauled with 2 horses. The cost of transportation has been reduced at least one-half. Whereas the supply of wood was formerly drawn from a territory not extending more than 5 miles out, to-day it is brought from as far out as 10 miles, and sold at a lower price. Products such as milk and butter, which formerly were not marketed, are now brought to town. The money for the building of these roads is raised by taxation. The county of Mecklenburg spends between \$40,000 and \$50,000 annually in building roads, and the people think the improvement is worth the money to them. There is no complaint about paying the road tax, though at the beginning there was a great deal of objection. (1039, 1041, 1044, 1045.)

Georgia.—Mr. HALE says there is great need of good roads in Georgia, but not much attention has been paid to the matter on account of the poverty of the country. Fine roads would be costly because of the scarcity of rock and gravel. (399.)

Mr. STEVENS says some of the counties of Georgia, notably the city counties, are giving very much attention to the improvement of roads. The country counties are beginning to take it up, and the cost of local transportation is thus greatly diminished. (916.)

Alabama.—Mr. POOLE says that the public highways of Alabama are miserable in many sections, so that it is hard to get from neighborhood to neighborhood or from town to town; but in some of the counties good macadam roads are being built, and wherever that is the case the disposition is to go back to the farms. The lands have also increased in value along these roads. (922.)

Louisiana.—Dr. STRUBB says the roads are probably worse in Louisiana than in any other State in the Union—first, because of the peculiar constitution of the alluvial soils, which are hard to drain, but easy to wear with the wheel, and, secondly, because of the absence of materials for road making, rocks being very scarce and building materials being made entirely out of clays. The police juries (corresponding to county commissioners) of the different parishes have been authorized recently to tax vehicles, and to levy a per capita tax, or require every man between the ages of 18 and 60 to work 12 days under an overseer on the road. The people are terribly in earnest about the road question. At a large agricultural meeting at Calhoun

in the summer of 1900 representatives of the road machines were present with their machines and rollers. The governor of the State made a speech on the subject, and Mr. Harrison, an expert sent down by Secretary Wilson, showed how to build roads by commencing the construction of a quarter of a mile of road. In the lower portion of the State the gravel system is usually adopted, the gravel being brought from the northern portion of the State or the middle of Mississippi. All wheels over 4 inches in width are exempted from taxation.

Dr. Stubbs says the riparian parishes have but one road each, which is on the bank of the river, the estates running back from the river to the swamps. There is a ditch for every hundred feet, and the ditch has to be bridged and the bridge kept in order. (784.)

6. Engineering problems of road construction.—*Requisites of a good road.*—Mr. HUTCHINSON says that theoretically a level road is the one to be sought after, but experience has shown that a one-half to 1 per cent grade is preferable, as that gives better drainage. The road should have the benefit of the sun and should, if possible, be located on the sunny side of a hill or forest. Distance should always be sacrificed in favor of grade. The grade should never break on a fill, but at either end, so as to keep as much water off the fill as possible. Ditches should be made alongside all embankments to prevent washes. In North Carolina Bermuda grass has been planted on all embankments, and it has been found that after 2 or 3 years water 2 or 3 inches in depth and several feet in width can run down an embankment that has Bermuda grass well set and will not wash out the embankment. (1039, 1044.)

Road building before and after Macadam.—Mr. DODGE says the stone road is the best road that has ever been put into general use. The ancient theory of road building was to prepare a heavy foundation and up to the time of Macadam a great deal of unnecessary expense and labor was put into this substructure. Macadam's plan was to dispense with any foundation of large stones. He found that when angular fragments of rock are reduced to nearly uniform size and spread on the road under pressure and moisture they will consolidate into one sheet of rock impervious to water. (691, 694.)

Equipment necessary for road building.—Mr. HUTCHINSON says that the outfit required for the building of macadamized roads should consist of a portable engine of 15 horsepower, a portable crusher with bins that can be set up, a road machine, a large plow, a harrow, a steam roller of not less than 12½ tons, a sprinkler, and teams. A roller is an absolute necessity. This outfit would cost about \$8,500. It would be possible, however, to start with a much smaller equipment. The road could be built with hand hammers, though not satisfactorily. Road building in Mecklenburg County was started with hand hammers, and there is no doubt that with sufficient care a good road can be built by hand. (1041, 1042.)

Process of construction of a macadamized road.—Mr. HUTCHINSON says that after the earth is removed from the road which is to be macadamized the bed should be thoroughly rolled and all depressions filled in. Then bed rock, broken so that it will go through a 3-inch ring, should be filled in to a depth of 6 inches. The second layer should consist of 3 or 4 inches of stone broken to go through a 2-inch ring. The third and last layer should consist of screenings or stone less than 1 inch in diameter, and should be from 1½ to 2 inches in depth. The whole should then be flooded with water. Each layer is rolled, the roller having a pressure of about 500 to 700 pounds per linear inch. In North Carolina the custom has been to put macadam to the width of 12 feet in the middle of the road, and to put a dirt track on either side. It would be better either to make the macadam from 9 to 10 feet wide, and have a single-track road, or to make it 16 feet wide for a double-track road. Mostly field stone, hauled in by farmers, is used in the construction of the roads. Blue stone is the most desirable stone to use, but a good deal of quartz has been used in North Carolina and has worn well. Some decomposed granite has been used and has been found very satisfactory. (1040, 1042, 1046, 1047.)

Cost of stone roads.—Mr. DODGE says there are many improved methods of handling the stone, which have reduced the cost of producing stone roads somewhat, but the cost is still high. The State highway commission of Massachusetts, after an experience of 4 years or more, reported a cost of upward of \$10,000 a mile for roads in sections where material was very abundant, including, however, the reduction of grades. One of the best roads Mr. Dodge has ever seen was built of trap rock in Baltimore County, Md., under the auspices of the Department of Agriculture, at a cost of \$2,500 a mile, but the material was right at hand in old stone fences along the road, and there were no hills to be reduced. (695.)

Mr. HUTCHINSON says that the cost per mile of building an average macadamized road has been figured out to be \$2,800. This applies to a graded road macadamized to a width of 12 feet and a depth of 9 inches. If the macadam were cut down to 9 feet in width it would cost 25 per cent less. (1044.)

Repairs.—Mr. HUTCHISON says that the repairing of a macadamized road requires more skill and intelligence than does the original construction. In repairing a road all the ruts and depressions are first filled in with broken stone and the surface of the road is broken up with a spiked roller. The surface is then thoroughly rolled and a coating of 3 or 4 inches of 1½-inch stone is put on to replace what has worn or been washed away. The repairing costs about \$400 per mile. In Mecklenburg County there is a road inspector whose business it is to go about from one road to another and report needed repairs. (1040, 1042.)

Destruction of roads by narrow-tired wagons.—Mr. HUTCHISON says that the greatest destroyer of a road, stone or earth, is the narrow-tired wagon with axles of even length. The costs of repairs to streets and roads in a few years could be cut down to 50 and 75 per cent in city, town, and country if the broad-tired wagon with short front axles were substituted for those now in use. On macadamized roads the tests show that frequently there is little difference in draft between the narrow and the broad-tired wagon. On earth roads there is a difference of from 20 to 50 per cent in favor of broad tires. (1040, 1041.)

Oyster-shell roads.—Mr. DODGE says the oyster-shell roads in the vicinity of Baltimore are very nice, but are not sufficiently hard to be durable under heavy traffic, and have to be replaced. (703.)

Steel-plate ways.—Mr. DODGE says that while the macadamized road is the best road developed so far, he believes it can be very much improved upon as to durability, the power required, and the original cost. Mr. Dodge has experimented with steel-plate ways, and thinks it very likely that when steel is sufficiently low in price very durable roads can be constructed requiring a diminished power to move the vehicle, and greatly reducing the cost of transportation. The plate way consists of 2 parallel plates 8 inches in width on a concrete foundation, and a sufficient distance apart to receive the wheels of vehicles of ordinary gauge. It will last indefinitely; in Canada a bridge equipped with plate ways of soft iron has been in use for over 30 years with very little wear. The cost of the steel at the prices prevailing before the late increase would be about \$3,500 a mile, and the road would cost, complete, about \$5,000 a mile, not including cuts and fills. The space between the rails has to be macadamized. Mr. Dodge does not recommend the use of the plate way at the present time; he does not think it would be the most desirable road, except in level countries destitute of other materials for road use. Engineers say it takes only one-fifth the power to move a vehicle over steel that is required on macadam roads.

Mr. Dodge made a test of the steel-plate way on the exposition grounds at Omaha in 1898. The Studebaker Wagon Company had made a test on a common road, showing that it took 20 horses to haul a load of 11 tons. Mr. Dodge put a load of equal weight on a train of 3 wagons and it was started and moved easily by one small horse, showing a ratio of about 20 to 1 in the power required. The horse moved about 22 times his weight, and Mr. Dodge believes that a strong animal could move 50 times its own weight. Ordinarily a vehicle carries a weight only about equal to that of a team; a load double the weight of the animals is an unusually large load. (691-693, 699.)

Mr. Dodge admits that the gain in power is not as great on a grade as on the level. Sliding friction can be eliminated and rolling friction diminished, but the power required to raise a weight vertically can not be diminished. He does not think a team could pull more than 50 per cent more up a steep grade on a steel track than on an ordinary road, but in at least two-thirds of the country the roads can be made nearly level. The reduction of grades to 3 per cent, if possible, is recommended. (694.)

6. Recent road-improvement laws.—Mr. DODGE says that in many of the road-improvement laws passed in late years two methods of initiating improvements are provided for: (1) Resolution of the county commissioners, and (2) application of the abutting property owners. In the latter case the property owners bear the expense, or in some cases 15 per cent of the expense, the rest being paid in other ways. (697.)

Mr. Dodge says the State of Ohio has had the best road law for the construction of roads by localities, but with the new idea based upon changed conditions of population and wealth and the longer distances to be covered the Ohio laws are not as satisfactory as some others. Massachusetts is the only State which has a law requiring the entire State to bear the burden of road improvement, and even there the locality bears the expense of reducing the grades. The New Jersey law, dividing the cost of the improvement between the State and the locality, is producing wonderful results. It was the first of the State-aid laws passed since the revival of road building and has been quite generally imitated. New York has passed a law which, though substantially the same thing, is claimed to be something of an improvement. New York has also passed a constitutional amendment forbidding the use of prison labor for

manufacturing commercial articles, and Mr. Dodge predicts that it may therefore become the first State in road building, as it is in population and wealth. (702, 703.)

The State of Ohio had a temporary highway commission, but it was not authorized to proceed to construction. Massachusetts has a permanent commission which in June, 1900, had been constructing roads for 4 years or more. Maryland has recently appointed a commission which has made a very elaborate report. (700.)

Mr. Dodge submits a copy of the New York road-improvement law of 1898 and recommends it as the most satisfactory State-aid law yet passed. The law provides that one-half the expense of road construction shall be paid by the State and one-half shall be a county charge in the first instance; 35 per cent of the cost of construction shall remain a general county charge and the remaining 15 per cent shall be assessed upon the owners of the abutting lands in proportion to benefits if the road is built on petition of the landowners, otherwise it shall be a charge upon the town. The State engineer and surveyor has general charge of the construction of roads, and is required to collect information on the subject, advise with local officers and other persons interested, cooperate with highway officers, and hold at least one public meeting annually in each county. (704-706.)

Mr. HAMILTON testifies that the Pennsylvania law of 1897 provides for a uniform system of road supervision. It contemplates the election of boards of supervisors composed of 3 persons, 1 to be elected each year and to serve for 3 years. State aid is provided for, and road masters are made responsible for their sections. The law is inoperative (January, 1900), because it requires an appropriation of \$1,000,000 which it has been impossible to make, but a board has been appointed to make a report on the road question to the legislature. (370.)

7. Distribution of cost.—Mr. Dodge says that for the last two generations the cost of road construction has been borne by localities. In nearly all the counties of Ohio where there has been any improvement at all the cost has been borne in the immediate locality. In Preble and Shelby counties, where there are no great cities, many roads have been built. In Shelby County, he believes, more than \$2,000,000 has been expended. On the other hand, Hamilton and Cuyahoga counties, which have the largest population and the greatest wealth of any counties in the State, have in the past built almost no roads. Roads are now being built in these larger counties, but the system of taxing the entire property, including the city, has been adopted.

Mr. Dodge says that a good deal more than a half of the wealth of the country is concentrated in the cities. In New York 90 per cent of the taxable property is in the cities of the State, and only 10 per cent of the taxes are paid by those living in the rural districts. Cleveland, Ohio, pays 80 per cent of the taxes of Cuyahoga County. The necessary amount of money can not be raised by the old method of making the community bear the entire burden. Where land is cheap, as it is now in most places, it can not bear the entire cost of expensive roads, and there must be some additional contribution. Mr. Dodge thinks the locality should contribute one-third, the State one-third, and the United States Government one-third. (697, 698.)

Mr. Dodge feels very certain that the old idea of leaving the matter of road improvement to townships or districts within townships is a thing of the past. It has become a matter of general concern, and the burden is too great for local authorities. When half the wealth and people are concentrated in centers of population, and when city people with automobiles and bicycles want to get out into the country as much as the people outside want to get in, it is just and necessary that they should contribute to the improvement of the highways. Mr. Dodge has never known of a complaint from any of the cities where taxes are levied for the purpose. He is pretty well satisfied that the best way is to proceed by States, and that each State should have a commission. (700, 701.)

Mr. HAMILTON says it is the general feeling in Pennsylvania that it is impossible for the farming people to build the roads themselves. Merchants and manufacturers are interested in roads as distributing agencies, and hence it is proper for State taxes to be distributed in the interest of good roads. Farmers can not be taxed to the necessary extent. (370.)

8. National aid.—Mr. DODGE says road improvement has for two generations been considered a local question, and was properly so considered as long as animal power only could be used, because the length of the haul was necessarily short; but with the introduction of the bicycle, the automobile, and the suburban street car, which cover long distances, it is natural that there should be a change in sentiment. Not only has the League of American Wheelmen made a demand upon the national parties for good-roads planks in their platforms, but the President of the United States, for the first time in two generations, has brought the matter up in his message to Congress, and Senator Penrose has introduced a bill in the Senate authorizing a large appropriation for road improvement. (700.)

CCCXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. Dodge says the National Government has for generations contributed millions of dollars to aid water transportation, by canals and by deepening harbors and rivers and the water communication between the Great Lakes, and has given subsidies of land and credit to aid in cheapening transportation on the Western railroads. The Government has been very liberal so far as the long haul is concerned, on land and water, but in the improvement of highways we have fallen behind other countries. (701.)

9. Modes of lessening the cost of roads.—Mr. Dodge estimates that 99 per cent of the entire road mileage of the country is still practically unimproved. To bring all of this mileage up to a high standard would require an army of men and a greater revenue than would be required to pay and supply the armies of the world. In order to make the system complete the cost must be lessened, and the only ways to do so are by diminishing the necessary mileage and diminishing the cost per mile. (695.)

Diminution of mileage.—Mr. Dodge says the necessary mileage can be reduced in two ways: (1) Electric cars or cars propelled by other mechanical power can be so multiplied as to do a great part of the service which has heretofore been done by animal power, and so shorten the haul; (2) roads have been laid out to accommodate a population spread equally over the face of the country, about a mile apart in the West, though not so near together in the Southern States. The consolidation of population makes it necessary to carry products to the great centers of population instead of to villages in rural communities. Mr. Dodge estimates that in time 75 per cent of the people will live in cities and that the 25 per cent remaining in the country will be drawn to the cheaper and better means of transportation. He estimates that 5 miles will be the maximum and 2½ miles probably the average haul for wagons. (695, 699.)

Diminution of cost by utilizing convict labor.—Mr. Dodge believes that prison labor can be utilized on road work. The entire army of prisoners in jails, State prisons, and United States prisons could be utilized either upon the roads themselves or in preparing material to be used on the roads. Probably more than one-half of them could be employed in shops and inclosures manufacturing the materials—whether broken stone, brick, or steel—and the rest, especially those sentenced for short terms, could be utilized in the actual construction. At present convict labor is complained of by manufacturers and laboring men as unjust competition, but applied to road improvement it would be doing a work that can not otherwise be done and would add to the common wealth, besides being beneficial to the prisoners. Close guarding and confinement would probably not be necessary. Mr. Dodge has seen prisoners working in the South without any chains or balls or other visible indications of restraint except one guard in the distance with a rifle, and the foreman of the gang. They worked as well as any free labor he had ever seen, and he thought even better. He found that by giving a reasonable rebate in service for good conduct, little trouble was experienced from attempts to escape. Prison labor is also utilized in California and New York, at least in Oneida County. (696.)

Mr. Dodge says the Roman roads were built by slaves and soldiers. Peoples who have kept up large armies and had large numbers either of prisoners, of slaves, or of State employees have generally put them on the public works. The greatest works of antiquity were produced in that way, and some modern nations have taken the same view of it as the ancients. The Russian railroad to-day is built largely by the Russian army. (697.)

Mr. HAMILTON says a recent Pennsylvania law permits the prisoners in county jails to be taken out and worked upon the roads in the immediate vicinity. In California stone quarries have been secured, temporary prisons and strong inclosures built at the quarries, and the convicts set to work quarrying the stone and running the stone crusher. (369.)

Convict labor.—Mr. HUTCHISON testifies that the labor employed in road construction in North Carolina is, with the exception of the foremen and bosses, convict labor. The repairing of roads, which at the present time is done by the townships, is done almost entirely by free labor. In the opinion of Mr. Hutchison, road building is by far the best use to which convicts can be put. There is a special act in North Carolina, by the terms of which a judge, in passing sentence, can sentence a man to labor on the public roads instead of sending him to the penitentiary. Men sentenced for short terms, from 15 days up, are sent to labor on the roads. Long-term convicts sentenced for grave offenses are usually sent to the penitentiary. Probably the number of convicts sent to the penitentiary in Mecklenburg County would average 4 a year. When the convicts are sentenced to road labor they are put in charge of the county commissioners and the commissioners have absolute control over them. There is a county engineer, who is elected by the county commissioners, in charge of

the work, and there is a superintendent of convicts, who has whatever number of guards are necessary under him. The convicts work on the roads for about 11 months in the year. It would not be possible for them to work for so large a part of the year in a colder climate unless they could be put to work in the quarries. The convicts do not receive any compensation for their labor. It costs from 25 to 31 cents a day per capita to feed and clothe them, to provide medical attention, and to pay the expense of guarding them. It would cost anywhere from 30 to 60 per cent more to build the road if free labor were employed, the average rate in the section for free labor of the same class being about 60 cents per day. The use of convict labor on the highways has not, however, been instrumental in lowering the wages of free labor, has not interfered with any profitable employment for free labor, and has not had the effect of causing indisposition on the part of free labor to engage in the manufacture of roads. There is no reason to believe that convicts are given longer sentences because of the fact that they are sent to work on the roads. The convicts employed in road building live practically in camp. They have portable barracks, built of inch lumber, put up in panels. They work from sunup to sundown, the hours of labor being longer in summer than in winter. A great many of the convicts are made "trusties," and the chains are taken off. There is no system of surveillance used over the men while at work other than that of the guard. The trustees are obliged to stay in quarters at night, but are not chained in any way. The convicts prefer to work on the roads rather than to go to the penitentiary, and there is very little trouble caused by their attempting to escape. (1038, 1039, 1042, 1046.)

Mr. WHITE testifies that wherever there are workhouses in North Carolina the judges sentence culprits to the workhouse instead of to the penitentiary, and they go out and work on the farm. They work on the public roads in Wake County and on the streets in Raleigh, to the exclusion of many free laborers. Mr. White thinks the least possible evil as to competition of convicts with free labor results from work on the public roads. (431, 432.)

Mr. White says that in some of the Southern States the convict system is terrible. The homestead laws have multiplied crimes, and the punishment is severe. The result is that the penitentiaries are filled, a large number of the convicts being colored people. In Georgia most of the convicts are farmed out on turpentine farms, largely to the exclusion of free labor. They are also put in the cotton fields, upon public roads and canals, etc. They are hired out for a little more than the expense of keeping them in the penitentiary. A convict may misappropriate a spoon, knife, or frying pan during his stay with the lessee, and at the expiration of his time the lessee may agree not to have him punished if he will work for him 12 months longer. In South Carolina, and in other States, also, the convicts are farmed out. In North Carolina, on the other hand, several thousand dollars have been spent in the purchase of farms, and all able-bodied convicts not incarcerated for life are sent to a farm to work out their sentences, so that the penitentiary is about self-sustaining. Within the walls of the penitentiary the convicts make bricks, and there is a shoe factory. All the public buildings of Raleigh are made of convict-made bricks. The convict shoes have been confined to the convict farms, but are now getting into the stores. (430-432.)

XIV. GRAIN ELEVATORS.

A. In the Northwest.—1. **Economic function of elevators.**—Mr. BUDGE, of Grand Forks, N. Dak., says that, in order that the farmers may not always be at the mercy of the market some system of storage is necessary. In some cases large farmers or farming corporations have their own warehouses, but the average farmer is not able to build warehouses, and it is therefore necessary that he should ship through some grain dealer. Thus the elevator is an essential factor in the grain industry. Capital would be invested in an elevator and grain shipping business only as a source of profit, and when it is found that operating expenses can be reduced and facilities improved by operating a system of elevators along a certain railroad it is only reasonable to expect consolidation and the formation of systems. There is no monopoly, however, as several companies are generally represented in each town of importance, and they watch each other's doings. The competition has resulted in reducing elevator charges to the reasonable and uniform price of 2 cents a bushel. Mr. Budge believes that the present elevator system is of the greatest value to the agricultural interests. No doubt influential elevator companies can secure better accommodations for quick shipment and better prices at terminal points than individual shippers. In this way the farmer will profit to a greater or less degree. The great storage facilities lately provided by the large elevator companies and the Great Northern Railway will be of much value to the farmers by permitting the rapid shipment of grain, and

CCCXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

by providing a sufficient terminal storage so that grain can be held for a better market when desirable. (843, 844.)

2. Elevators in South Dakota.—Mr. JUMPER presumes that the number of elevators at the stations in Brown County, S. Dak., which is 36 miles-wide by 48 miles long, is about an average for the 3 States of North and South Dakota and Minnesota. There are in that county 20 railway stations where wheat is bought and shipped. At these stations there are 45 elevators, with a capacity of from 12,000 to 15,000 bushels each; 12 flat houses, with a capacity of 3,000 to 5,000 bushels each, and 3 flouring mills with large elevators attached. Thirty of these houses are owned and operated by the line companies—elevator companies having headquarters outside of the State. There are 12 different elevator companies operating in the county which have headquarters in Minneapolis. Twenty of the houses are owned and operated by independent parties. At two or three of the stations there are special loading platforms erected for the farmers, who drive up just as they do to an elevator and unload into the car. At other stations they must load from the regular depot platform, or if the ground is level they drive up to the side of the grain door. If the crop is large, nearly all of the houses are open; if it is poor, only about half are open. In 1899 nearly all were open; in 1900 only a little over half of them were open. In a good season the elevators handle about 50,000 bushels of wheat during the year. There are only two elevator railway companies in Brown County that have cleaners. They are at Aberdeen. (738.)

Mr. Jumper says that in Brown County, S. Dak., there are 12 operating elevator companies whose terminals and headquarters are in Minneapolis. These companies operate substantially all over the northern part of South Dakota. (734.)

Mr. Jumper says elevator companies always keep on hand wheat to cover storage tickets outstanding; if not at the same elevator where tickets were issued, at some other near-by point on the line. (738.)

3. Elevator combinations.—Mr. M. F. GREELEY, secretary of the Board of Regents of Education of South Dakota, testifies that an elevator "combine" exists throughout Minnesota and the Dakotas. The different elevator companies seem to have an understanding with each other, and frequently one man gives the prices for several lines of elevators. Occasionally two different lines of elevators are represented at the same place. These elevators are detrimental to the producers of grain, principally in that they regulate prices regardless of the demand, and can put them up and down in a way to give themselves an illegitimate margin. When farmers' elevators are erected the power of a line elevator company is used to crush them. They put up the price until the farmers' elevator can not do business, and make it up with interest afterwards. (939.)

Mr. Greeley intimates that the line elevators belonging to different companies work in harmony. It is understood that they pool their receipts, but Mr. Greeley does not know that they do. (940.)

By "line" elevators Mr. Greeley means the kind of which a long line is owned by one company. (939.)

Mr. Greeley says the complaint against the elevator combination is general wherever it has control, including Minnesota except where there are gristmills, local buyers, or other means of handling the business. (943.)

Mr. MORAN affirms the existence of a general elevator combination throughout the wheat-producing belt and declares it a detriment to the producing classes, enabling the elevators to set the prices paid at the local stations. The prices range from 1 to 11 cents a bushel below the price which a farmer could get if he loaded up a carload of grain and shipped it to a terminal market. This combination, Mr. Moran declares, exists in nearly every station throughout the wheat belt where there are no farmers' or independent elevators. Where one of these farmers' elevators is started on the cooperative plan the most intense opposition is often shown by the line elevators, which bid 1, 2, and 3 cents more than they can get for the wheat in the terminal markets, making up the loss by advantageous rates at other points, and by exacting further tribute from their helpless victims after the independent house is obliged to sell out.

The line elevators are further enabled to carry on this warfare through the aid they receive from the railroad companies (1) in the prompt supply of cars in the busy season, (2) in the refusal of many roads to grant sites for farmers' elevators, and (3) in rebates. Mr. Moran says the rebates are often given by the officers of the railroads, who are participants in the division of the profits of the line-elevator companies; but it is most difficult to secure evidence to prove the existence of these conditions, which are commonly known and understood. (717.)

Mr. PROM says the line elevators seemingly do not compete with each other; the price is the same at all, and they dare not go above it. By way of proof that the

elevators pool and are practically one, Mr. Prom says that a few years ago one superintendent was sent out to the different elevators in Milton, but that was such an evidence of the pool that now one is sent to each house. Mr. Prom knows that the same men hold stock in different elevator lines. (796, 798, 800.)

Mr. Prom testifies that there are 10 elevators in Milton, N. Dak., all line elevators. There are no competing elevator companies nor independent elevators. The elevators are seemingly not owned by the same persons, but by different corporations; but Mr. Prom suggests that the stockholders might be the same. (795.)

Mr. JUMPER, of Aberdeen, S. Dak., says he knows there is no elevator "combine" in his section, and no consolidation as to the fixing of prices, except that the elevator people agree to buy on a 3-cent margin. The Empire Elevator Company, the George C. Bagley Elevator Company, the Crown Elevator Company, the J. F. Whalen Elevator Company, and the Victoria Elevator Company all operate on the Chicago, Milwaukee and St. Paul Railroad system. The Bagley and Empire companies also operate on the "Soo." The G. W. Van Duzen Elevator Company, the Marfield Elevator Company, and the Atlas Elevator Company operate entirely on the Northwestern road. At every station on the Milwaukee system there are from 3 to 5 elevators owned by different companies. The farmer is not compelled to patronize any of these companies; he can have a car and ship independently, and receives the same consideration from the railroad companies that the elevator companies receive. (735.)

Mr. BUDGE says there are not as many elevator companies in North Dakota as there were. The Peavey Elevator Company is buying up a good many of them. There are still a few independent elevators, but very few of these are owned by farmers. "The farmers have built some elevators in partnership among themselves, but they always let them go." (853, 854.)

Mr. Budge says that 2 elevators in Grand Forks are owned by different companies, and compete with each other in buying grain, but the price is fixed in Duluth. Mr. Budge does not think the line elevator men ever get together and fix the price themselves. The price can generally be figured out from the Duluth market report by allowing for freight rates and 2 cents for the elevator. (855.)

Mr. PRATT, of Aberdeen, S. Dak., formerly general agent of the Empire Elevator Company of Minneapolis, says he has never seen anything of a combination between the elevator companies of the Northwest to fix prices, and does not think there is any elevator trust. Although a certain price is fixed upon, it is occasionally broken. (724, 725.)

4. Storage charges.—Mr. Prom, of Milton, N. Dak., says the storage charges at the elevators are the same as in Minnesota—15 days free, 2 cents a bushel for the first 30 days, and half a cent a bushel for each additional 30 days. (796.)

Mr. JUMPER, of Aberdeen, S. Dak., says the storage charges are a considerable source of profit to the elevators. Storage for the first 15 days is free; the rate for 3 months and 15 days is 3 cents; after that the rate is one-half a cent a month for the next 3 months, making the rate for 6 months and 15 days 4½ cents. For 9 months and 15 days it is 6 cents. The elevators store wheat all the year round and sometimes for 2 or 3 years. When the owner calls for his wheat after storing it the elevator company charges 2½ cents. That is called delivery. (739.)

Mr. PRATT, of Aberdeen, S. Dak., says there is no storage charge for the first 15 days in the elevator. Some buyers sometimes forget the time the wheat is put in and let it run a little longer—perhaps 30 days—for nothing. (728.)

Mr. BUDGE, of North Dakota, says the elevator companies charge more for storage at some seasons than at others. It depends on the shipments to Europe and to Duluth. In 1898 or 1899 the wheat was carried until the first of January without any storage charge. The storage fee is usually one-half a cent a month, plus insurance. (855.)

Mr. HANLEY testifies that Mr. Hill, of the Great Northern, reduced the minimum storage charge to half a cent, a reduction of \$1,560,000 upon the 208,000,000 bushels of grain that went through the elevators in the course of a year. (280.)

5. Cost of operation.—Mr. JUMPER, of South Dakota, says that when an elevator handles 50,000 bushels of wheat yearly, the expenses, including the pay of the man who operates the elevator and buys the wheat and of his helper in the busy season, amount to 1½ cents a bushel. If an elevator company has a line of houses there would be the expense of maintaining an office at the terminal point, traveling expenses, insurance and taxes on the elevator, and interest on the money needed to operate it, which will add three-fourths of a cent a bushel, making the total cost 2½ cents. If the elevator handles 65,000 bushels the expense should be calculated at a quarter of a cent less, or 2 cents a bushel; if it handles 80,000 bushels, the expense would be about 1½ cents; if 100,000 bushels, about 1¼ cents. If a house handles only

COCXX THE INDUSTRIAL COMMISSION:—AGRICULTURE.

35,000 bushels, as in a poor year, the expense will be increased a quarter of a cent. When a crop is light and the amount to be handled small, the expense can not be reduced in proportion. Very few houses handle 100,000 bushels. (738.)

6. *Card prices.*—Mr. MORAN complains of the inability of the farmers to set a price upon the wheat they raise. They are obliged to go to the elevators and ask what they are paying for wheat, and to whatever elevator they go the price is the same. (718.)

While Mr. GREENEY believes that as a rule prices are governed by supply and demand, he says the elevators have arranged it so that they receive the prices every morning from headquarters, and those are the prices that govern. The price of grain comes to the railroad agent, who hands a copy to each of the line-elevator representatives from the same telegram. (939, 940.)

Mr. BUDGE, of Grand Forks, N. Dak., says that the price of wheat at that point is generally fixed by the Duluth Board of Trade. The prices are telegraphed every morning. (855.)

Mr. FROM, of Milton, N. Dak., says all the line-elevator companies in Minneapolis have given it into the hands of one man to fix prices; that man determines what the prices are to be from the market of the day. He has to consider reports from the Argentine Republic, and the condition of the weather and rains in the Northwest, and be the sole judge whether the price ought to go up or down. If the price is raised he generally writes to the country representatives; if the price goes down he wires at once. The price of grain is telephoned daily from Fargo to the agent at one of the elevators in Milton, and he is supposed to go at once to all the other agents and give it to them. Fargo receives the price from Minneapolis; the price is not received from Duluth or from any other point. (795.)

Mr. PRATT, of Aberdeen, S. Dak., formerly general agent for the Empire Elevator Company, of Minneapolis, testifies that the price of wheat is made up in Minneapolis by a board of three or four men; the elevator men, the commission men, and the Chamber of Commerce being represented. A telegram is sent to the representative at Aberdeen, Mr. Jumper, and he sends out prices on cards for the different grades of wheat. If he can not get the card to its destination in time he sends a telegram. (724.)

Mr. JUMPER understands that there is a committee of three at the Chamber of Commerce in Minneapolis, one a speculator in "wind" wheat, representing the Chamber of Commerce, one appointed from the elevator men, and the third appointed from the commission men, who are rivals of the elevator men. When the trading is over for the day these three men meet and agree whether the price of wheat shall be advanced or reduced throughout Minnesota and the Dakotas. If the price has advanced on the market that day their clerk immediately wires this advance into the country. It is wired, for instance, to Aberdeen, and is sent out by the Aberdeen representative to a territory 200 miles east and west by 125 miles north and south. An advance or reduction is never less than 1 cent, although the markets at the terminal points may change one-half a cent. Mr. Jumper does not think this committee has very much power, because the elevator men endeavor to keep the price about 3 cents (plus the freight) less than the cash price of wheat on track in Minneapolis. When there is an advance of a cent, and sometimes when there is an advance of half a cent, if the margin is a little too large, the country market will be advanced a full cent; or if there is a reduction of a half cent and the margin was a little too narrow, there will be a reduction of a cent. The margin varies from year to year with the grade of the wheat; it was larger than usual in 1900-1901, because the wheat was very poor as a result of getting wet after being harvested. When the crop is first class the margin is sometimes a good deal less. (730.)

Mr. Jumper receives the card price at Aberdeen and furnishes it alike to the line companies, independent elevators, and mills. If his instruction from Minneapolis is to distribute the price by wire, he immediately sends it by telegraph and telephone to the different stations. These messages are then followed by cards in the evening mails. The telegram either reduces or advances the price 1 cent or more, as the case may be. It is arranged that it shall be sent to one buyer at each station to save expense, and he immediately notifies all the others. Individual shippers of grain can get the card price by paying their share of the expense, just as the elevators do. (736.)

Mr. Jumper explains that no elevator company and no buyer is bound by the card price. They invariably pay a cent and sometimes a cent and a half more for a good quality of wheat than for a poorer quality. At 5 important stations, one of which was Aberdeen, they paid 2 cents above the card price for the *ganfre* crop in 1900, because the wheat was very much better there than at the other stations. (735, 736.)

Mr. PRATT says that very often instructions are sent out to the buyers to get their share of the wheat, and they will pay from 1 to 3 cents more than the card price. Sometimes the market is disturbed in this way for a month or so. (725.)

7. Manipulation of prices.—Mr. PROM is quite sure that the elevator companies have a good deal to do with bearing the market, though he has no evidence to that effect. (800.)

Mr. JUMPER has seen no evidence of any disposition on the part of the elevator companies to "bear" the price at certain seasons of the year. He thinks the understanding of the committee at Minneapolis is that the margin shall be just about the same the year round. (736.)

8. Profits of elevators.—Mr. JUMPER states the margin taken by elevators buying wheat in South Dakota, with Minneapolis as the market (the freight being deducted), as follows: 1893, 3.2 cents; 1894, 3.4 cents; 1895, 3 cents; 1896, 3.3 cents; 1897, 3 cents; 1898, 3.1 cents; 1899, 3 cents; 1900, 3.4 cents. (732.)

Mr. PROM testifies that the elevator company's profit on one car of flax (1,000 bushels) recently shipped from Milton, N. Dak., was \$450. This exceptional profit was due to the way the flax was bought. There were only two grades, No. 1 flax and "rejected" flax. (799, 800.)

9. Elevator discrimination.—Mr. PROM testifies that in the winter of 1898 and 1899 the elevator companies bought wheat 6 miles below Milton at 2 cents above the price at Milton, and also paid higher prices 6 miles west of Milton. In consequence all the trade went away from Milton, and the town was as dead in the middle of the busy season as on a summer's day. The merchants and business men combined and employed a private buyer, hired men, and arranged a place for loading wheat. The superintendent came up to see about it, and a better grade was promised. This action, therefore, raised the prices to an equality with the other towns; but the threat was made that if opposition were continued hardware stores and general stores, as well as wheat houses, would be established. (798.)

10. Mixing of grain.—Mr. MORAN says the terminal elevator facilities of the line elevators also give them a great advantage, enabling them to take a customer's grain for storage and charge him for it, while at the same time mixing it with an inferior grade and delivering the degraded grain to the customer. The rules of the board of trade will allow the elevator to deliver such grain as long as it passes the contract grade, commonly known as "skin grade," although there is often a difference of 1 to 2 cents a bushel between the value of the best and poorest wheat of the same grade. The profit to the mixer is often greater per bushel for mixing than the profit of the farmer who produces the grain. (717, 718.)

Mr. MORAN testifies that the mixing of grain is done at the terminal elevators. The foreign buyer does not receive No. 1 hard as it comes from the virgin soil, because the elevator men mix it at their terminal points; and there is quite a difference between the best grain and that which barely touches No. 1. The elevator men reduce the grain to the lower level so that it will simply pass the grade. (719.)

Mr. JUMPER says that, knowing the expense of operating an elevator, he does not see how the elevators can make very much money in the actual buying of wheat at the initial point. He thinks that one way the elevator men have of making money is by mixing the grain at the terminal points, in order to raise the grade of the poorest quality. There is not very much mixing by the buyers at the initial points; there is no chance for mixing there. (735.)

Mr. PRATT, of Aberdeen, S. Dak., says the elevator companies mix grain to some extent, but not a great deal. It has to be cleaned and the shrunken wheat taken out. It is mainly export wheat that is mixed. (726.)

Mr. BUDGE, of North Dakota, says the mixing of high with low grades of wheat to bring up the grade is done after the wheat is sold at St. Paul and Duluth, not in the country. (855.)

Mr. HANLEY says Minnesota grain is so degraded by the time it reaches the selling point that its value is gone. If it were removed from the control of the many hands through which it passes, Minnesota grain would have a premium of 3 or 4 cents a bushel in the markets of the world. (282.)

11. Drying of wheat.—Mr. BUDGE, of North Dakota, says that when farmers ship wheat that is shrunken, or a little damp, it is taken into the mixing and drying houses and worked up a grade. That is where the elevators make their money. The farmer does not get the benefit of the improvement, and sometimes finds fault with his own carelessness. (855.)

Mr. PRATT says there is some wheat going to Minneapolis that has to be handled a good many times to keep it from heating in the bin. Some of the elevator systems are equipped for drying damp wheat. There are elevators in Minneapolis that do

CCXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

nothing else but buy low-grade wheat and handle it with driers. The regular elevator companies turn damp wheat over to them rather than put it in their own houses. (725, 726.)

12. *Switching charges.*—Mr. BUDGE testifies that at Minneapolis there is a charge of one-half a cent for transferring wheat to another elevator or mill; at Duluth there is no charge for switching. (856.)

13. *Sale of futures by elevators.*—Mr. MORAN complains that the elevators, becoming traffickers in the products of their customers, are enabled to sell futures to such an enormous extent that they can sell millions of bushels of "wind" and charge the regular fixed charges of storage and commission on grain that never existed. This is done in such vast volumes that the sales of "wind" in one day will amount to fully 600,000,000 bushels, or as much as the entire crop of the nation. This amount is sold for 300 days in the year, and is one of the greatest influences in destroying the value of farm products. (718.)

Mr. PRATT, of Aberdeen, S. Dak., says the money in the elevator business is not all made in buying wheat in the country. When the elevators get wheat on hand, if future wheat is high, not wanting to carry the wheat themselves, they sell it for delivery in January, February, March, or as far ahead as May, and that gives them a little profit. Then when the time comes they sell the actual cash wheat to other parties. The future sales are simply to protect them on their purchases. As a rule, the elevators do not carry any wheat for speculation. (726, 728.)

14. *Relations of railroads to elevators.*—Mr. PROM has no doubt that there is a community of interest in the management of the Great Northern Railroad and the elevators. He knows of one man who has stock in the Great Northern road who is heavily interested in the elevator companies, but the operation is entirely separate. Mr. Prom says it is not the general belief among the farmers that the railroad companies control the elevators, though he believes that was formerly the case. None of the elevators are owned by the Great Northern Railroad, but Mr. Hill may have an interest in them. (796, 800.)

Mr. M. F. GREELEY, of South Dakota, complains that, while the railroads have used the farmers very fairly in most ways, when the elevators undertake to "hold up" a community the railroads sometimes lend a hand. "If the railroads would keep their hands off, if they would not hold us while these elevators rob us, we would be all right." Mr. Greeley goes on to explain that the farmers would in that case put up their own elevators, at which the only profit demanded would be the buyer's salary; but when the railroads will not permit the building of these elevators the farmers are handicapped. In Gary, S. Dak., there are 2 line elevators. There was recently a movement for putting in a people's elevator, and one man wished to put in an independent elevator. A meeting was held and the railroad commissioners and railroad people came with attorneys and heard witnesses, and finally decided that the site for the elevator would not be granted. They said the amount of grain was not sufficient for 3 elevators. Mr. Greeley admits that the 2 existing elevators were sufficient to handle all the grain they received, but says there would have been a great many more bushels if there had been a farmers' or an independent elevator, and there would have been better prices. Farmers frequently hauled wheat away from that territory. Mr. Greeley says that if the people are foolish enough to build too many elevators, he can not see why the railroads and railroad commissioners should insist upon enlightening them. (939, 940.)

Mr. MORAN thinks the railroads and their officers are not, as a general rule, interested in the elevators; but some of them are. (721.)

Mr. JUMPER, of Aberdeen, S. Dak., knows of no combination between the railway and elevator companies. Fifteen or 20 years ago the elevator companies were owned by some of the officials of the Milwaukee road; but he does not think that they have had any interest in them during the past 10 or 12 years, or that the owners of the elevator companies own any stock in the railroad. (737.)

Mr. Jumper thinks there was no way to get the elevators and Fairbanks scales built in the early days in South Dakota except by the railroads building them. President S. S. Merrill, of the Milwaukee road, encouraged parties to put up elevators in advance of the production of wheat, and the railways assisted in putting them up. Some of the officials of the road invested in them, but the investment lasted only a few years. The elevators and scales were really projected and built by the railroads and by parties interested as big shippers. (737.)

Mr. BUDGE testifies that the railroads have not built elevators at Grand Forks or controlled the weighing. The managers of the two elevators at Grand Forks have been citizens of the place for several years. No pressure was brought to bear to cause the decrease in the number of elevators or force the elevators out of business, except that when the other roads came in there was no business for the elevators. The

farmers loaded their wheat on the side tracks and saved 2 cents a bushel. The two existing elevators are sufficient; the others were torn down and moved away. Mr. Budge thinks that if he desired to go into the elevator business he could procure an elevator site and switching facilities. (856.)

15. Railroad rebates.—Mr. PROM says the elevators formerly got a rebate from the railroad at the end of the season. One line of elevators got a rebate of 2 cents per hundred pounds in cash. Mr. Prom believes the system of rebates has been discontinued on the Great Northern at noncompetitive points, but he believes, from inside information, that it still exists where there are competing lines. (800, 801.)

Mr. JUMPER, of Aberdeen, S. Dak., says he has never been able to find out whether the line elevator companies get railroad rebates, though he has tried every possible way to ascertain. (737.)

Mr. MORAN testifies that he knows of one instance in Browns Valley where an elevator man having an independent elevator of his own received a rebate from the railroad, given him as a check for labor rendered, though he had performed no labor for it. (722.)

16. Country buyers.—Mr. PROM says the managers of the country elevators are not permanent citizens of the towns in which the elevators are situated, but go from point to point. When a man is disliked he is sent to another place. (802.)

Mr. GREELEY says the elevator companies frequently hire a man from the particular community to run the elevator, but generally the managers are men who have been in their business. (940.)

17. Grading of grain by country buyers.—Mr. BUDGE, of North Dakota, says that when grain is sold to the elevator the grade is fixed by the elevator buyers, generally young men, hired by the company for that purpose, who are under bond to keep up the grades and weights. The grade depends on the color of the wheat as well as the weight. The inspectors at Minneapolis and Duluth are State officers, and appeal lies from the chief inspector to a grain commission. (854.)

Mr. JUMPER, of South Dakota, says the buyers try to please the farmers, because they want to get the wheat. He has known of buyers being discharged by the elevator company because they favored the farmer too much. (735.)

Mr. PROM says the wheat is usually graded as it comes in loads from the thrashing machine. The agent of the elevator company jumps upon a load of wheat, takes a handful and looks at it, and says what it ought to grade; and to verify the grade he weighs it on a little scale called a tester to see if it comes up to the weight of No. 1 hard. If the farmer is not satisfied he goes to another elevator, and the agent will ask him what the other offered him, and will not give him any better grade. Sometimes the farmer succeeds in getting a better grade; but the man who buys at a better grade is reported at once, and the superintendent comes up and overhauls him. Mr. Prom thinks the greatest difficulty of the farmer in the grading of the wheat is that it is left in the hands of incompetent men. (796, 797.)

Mr. Prom testifies that the elevators never buy a bushel of No. 1 hard wheat in Milton. The wheat has to be of excellent quality in order to grade No. 1 Northern, and No. 2 is the best grade the farmers can usually get in that section. Wheat good enough by weight to be No. 1 hard is lowered in grade if the kernels are a little wrinkled, irregular in shape, or a little dirty in the end. There is a difference of 1 cent in price between No. 1 hard and No. 1 Northern, 4 cents between No. 1 Northern and No. 2, and 5 cents between No. 2 and No. 3, so the farmers lose from 4 to 9 cents a bushel. (797, 799.)

Mr. Prom testifies that if one elevator company's agent buys wheat for a better grade than that at which the other elevator agent would have graded it, the fact is reported to Minneapolis, and he is complained of; then the superintendent of his elevator line writes and reprimands him. (796.)

Mr. PRATT, of Aberdeen, S. Dak., says wheat is bought in the country by sample. The man who is handling wheat can tell the grade without any test. He will test the grain for any farmer who wants it tested, but farmers very seldom ask to have it tested. (726.)

Mr. Pratt says there is sometimes a great deal of wheat the character of which it is hard to decide. The elevators sometimes take No. 2 as No. 1, or No. 3 as No. 2, and at Minneapolis they will not get the grade it was bought for. There is a dockage for dirt, of whatever the buyers deem proper; but some buyers, for the sake of getting the wheat, will charge less dockage than they should. (725.)

18. Grain inspection in Minnesota.—Mr. JUMPER says South Dakota has no inspection laws. The grain is inspected according to the laws of Minnesota, which has an inspection board, the chief inspector being appointed by the governor. The grading of No. 1 wheat is according to its weight and the amount of hard wheat. No. 1 must weigh 57 pounds to the bushel and contain a good proportion of hard wheat;

CCCXXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

No. 2 must weigh 56 pounds; No. 3, 54 pounds. The other grades are determined according to the condition. (734.)

Mr. Jumper says that when the farmer ships his own grain it is graded by the State inspector at Minneapolis. On the arrival of the wheat the agents of the inspector break the seals and open the doors of the cars. A long stick with 6 or 8 little tin boxes, or little holes in the stick with tin covers, is run down into the grain to the bottom; then a knob is turned and the little boxes fill. The stick is then drawn up and the little boxes opened. In this way a lot of bad wheat at the bottom or in the middle would be detected. If the wheat looks all alike it is thrown into a box or bag. It is then weighed, and if it is very dirty a pound is deducted for dirt; if it is not very dirty half a pound is taken off. If the farmer is not satisfied with the grade his commission man can call for a reinspection. Inspectors perhaps take a little more pains a second time and the second inspection is final. (734, 735.)

Mr. Prox complains that the farmers of North Dakota are absolutely under the thumb of the governor of Minnesota, who has the appointment of the grain inspectors at the terminal points. He considers the inspection of grain in Minnesota the greatest evil from which the farmers of North Dakota suffer. The North Dakota wheat does not always get the grade the Minnesota wheat gets, though it should be a better grade, being used for mixing to raise the Minnesota grades. The elevator men influence the inspectors by giving their own judgment as to the grade of carloads of grain. (799, 801.)

Mr. Prom states that Duluth accepts the grading of the Minneapolis market as a rule, but not always. The line elevator men, who have the faculty of "standing in" with the inspectors, can make an immense amount of money, and did so in the flax shipment in 1900. The only grades were No. 1 and "rejected," and all the flax bought in Mr. Prom's vicinity was bought as "rejected" at a low price, although it was a good grade of flax. At Minneapolis it was graded No. 1 and shipped to Duluth at a clean profit of 55 cents a bushel. Mr. Prom says he has evidence from confidential sources of collusion between the inspectors and elevator men. (801.)

19. Storage tickets as security for loans.—Mr. JUMPER, of Aberdeen, S. Dak., says the local banks will accept storage tickets and loan within 5 or 10 cents of the price of wheat. If wheat is 50 cents they will loan 40 cents if the market is steady. (739.)

Mr. PRATT, of Aberdeen, S. Dak., says the elevator men have to borrow some money to move the wheat crop. Wheat receipts are the best security, and they get money very reasonably. There is some Montreal money in Minneapolis for the wheat business. When the Canadian banks helped move the Western grain, it was an advantage to the farmers, because it enabled the elevators to act and helped to continue business. (729.)

Mr. PROM testifies that in the most active time of buying wheat the elevator directors borrow money at the banks on their storage tickets, or their agents draw on the houses for any amount they want. Sometimes, when a heavy movement of wheat is expected, the elevator company ships \$2,000 in money to the agent, but that is undesirable, and they allow him to draw through the bank. (802.)

20. Independent elevators.—Mr. HANLEY says the farmers are building elevators all over the Northwest. They form stock companies and run the elevators separately, and the National Farmers' Alliance and Industrial Union stands back of them and gives them its support. In 1898 there were about 143 farmers' elevators building and in operation. In 1899 Mr. Hanley had promoted about 92 at the time of his testimony (August 12). It was a bitter fight to get the railroads to the point of giving any facilities, but they are now giving the farmers all the encouragement possible. Mr. Hill, of the Great Northern, gave them right of way on all his lines, and the other companies were obliged to do the same, though some of them were very reluctant to allow the elevators to be built. At noncompetitive points the farmers sometimes have difficulty in getting sites. The farmers' elevators pay the highest prices, less 2 cents for operating charges. (279, 280.)

Mr. MORAN testifies that the National Grain Growers' Cooperative Association is erecting farmers' elevators on several railroads, including the Milwaukee, the Great Northern, and the Northern Pacific. There are probably not over 150 of these elevators. They are in Minnesota and the Dakotas. There is 1 in Browns Valley, 1 in Beardsley, 1 in Chokio, 1 in Graceville, 1 in Ortonville, and a few others near there. They are usually built on ground belonging to the railroad, although in some places the railroads refuse the site. After the elevators are in operation the railroads are generous in giving shipping facilities, though sometimes there is a car famine, when all are unable to get cars. The grain from these farmers' elevators is shipped to the commission men in St. Paul and Minneapolis. Mr. Moran thinks that in some instances they do not get the same freight rates their competitors get. The rules in

regard to the time allowed for loading cars, grading of grain, etc., are generally about the same as at other elevators. The buyers at these elevators determine the grades and the price to be paid. They receive the card price of wheat, usually 3 or 4 times a day, by wire from the commission men and dealers, and they ship principally to Minneapolis and Duluth. There is no trouble about the handling of the grain at the terminal point. The greatest advantage possessed by the competitors of these farmers' elevators, however, consists in having terminal elevators. (722, 723.)

Mr. JUMPER, of Aberdeen, S. Dak., states that if a number of farmers wish to erect an elevator they apply to the railroad company, pay \$5 ground rent, just as the line elevators do, put up their elevator, and operate it to all appearances just the same as the line companies. Mr. Jumper knows of no obstruction placed in the way of these independent companies by the railroads. South Dakota has a law compelling the railroads to give these facilities to independent elevators. This law was the result of an indisposition on the part of the railroads to give such facilities, and Mr. Jumper thinks the inclination to favor the line elevators still exists, though the opportunity does not. (736.)

Mr. Jumper testifies that at nearly every station in Brown County there is an independent elevator or flat house, owned and operated by independent buyers. He thinks there is no obstruction placed in the way of the successful operation of these independent elevators. (736.)

Mr. PROM, of Milton, N. Dak., testifies that persons desiring to build an independent elevator must apply to the railroad company for a site, and they are very slow in getting it. It is almost impossible to get any facilities for shipping or handling grain independently. In order to ship grain it is necessary to have a loading platform to bring the wagons to the level of the car floor. The railroad company compelled the elevators to build one, but without designating the place; so it was put out where it was so steep the farmers could not drive up, and in such a form that it was impossible to use it; so residents in the locality had to build another and make the company a present of it. The farmers also combined to build a farmers' elevator and applied for a site, but did not get it; "the railroad people will not give you reasons; they simply stand you off. * * * Then you go to the railroad commissioners, and if you have nobody that stands in with them you do not hear anything from them." The railroad commission's investigation is described as consisting of a flying trip on a private car, with a 2-minute stop. (797.)

Mr. Prom testifies that an independent elevator was built at Lakota, but the line elevators decided that it should be killed. The merchants of Lakota stood behind it to help the farmers, and the old line elevators started general stores in Lakota, handling all the goods the local merchants handled and selling them at cost, for revenge. The result was that the merchants were obliged to cease their support of the independent elevator, and the elevator gave up the business. (798.)

Mr. Prom says the line elevators always put up the price of grain to freeze out an independent elevator. He thinks this was done at Lakota in the beginning. After an independent elevator fails the price is immediately lowered. (798, 799.)

Mr. Prom says better prices would be obtained from an independent elevator; the farmers would not have to take card prices; they would not have to pay the margin that the elevator companies get, which is sometimes too large, especially on the lower grades. They are supposed to do business on a margin of $3\frac{1}{2}$ cents for No. 1 hard, and on the lower grades the margin is 2 and $2\frac{1}{2}$ cents. (797.)

Mr. Prom says the independent elevator would create competition; an honest man would give a better grade for wheat, which means 2 or 3 cents a bushel for the farmer, and he would not buy on such a wide margin, and would give the farmer what he should have in weight. When it is possible for the farmer to get a car he makes from 5 to 10 cents a bushel on his wheat. A private elevator would help him to do that without waiting for the car; now the farmers have to hold the wheat in granaries until spring, when cars are plentiful. (798.)

Mr. GREELEY, of South Dakota, says the line elevators do not compete with the other elevators in prices. There will be lax seasons when they will pay the same, but when the wheat is really coming in they do not, and thousands of bushels are diverted to those places where they have the other elevators. The difference in price has been found to be from half a cent to a cent and a half a bushel, and sometimes much more; in some cases enough to rob the farmer of all his margin of profit. (939.)

21. Independent shipments.—Mr. PROM, of Milton, N. Dak., says that if the farmer does not feel like accepting the price offered for wheat, he can keep his wheat, or try to get a car and ship it to a commission firm in Minneapolis or Duluth. The railroad officials will furnish a car if they can not help it, but are not very eager to furnish cars to private shippers; the line elevators get the preference. When there

CCOXXVI THE INDUSTRIAL COMMISSION;—AGRICULTURE.

was very little wheat, during the dry season of 1900, there was an abundance of cars and the company was anxious to do more business, but during a busy season the farmers can not get cars. The rule of the company is that farmers and elevator agents wanting cars must order at 6 o'clock Saturday afternoon. The elevator agents are there beforehand, and put in their orders for so many cars. The first man who orders is first served, and all the elevator companies order first. Only a limited number of cars are sent up, and if there are not enough to go around, the farmer gets none. (795, 796.)

Mr. Prom says that when farmers ship their grain independently they simply dump it into a car, seal the car, consign it to a house in Minneapolis or Duluth, and leave it absolutely in the hands of the commission merchants to get what they can for it. The commission men superintend the inspection of the grain by the State inspectors and appeal if it is too low. When a car is shipped to a private commission man he takes a sample to the chamber of commerce at Minneapolis and offers it for sale. The wheat that is graded No. 1 hard in the country never sells below that grade. The men who need the wheat are willing to pay for No. 1 hard, though the inspector may say it is all No. 2, so the farmers prefer to take their chances on the merit of the grain. Wheat graded No. 2 at Milton will often sell in the Minneapolis market as No. 1 hard. (799, 800.)

Mr. Prom says the private commission merchants in Minneapolis or Duluth have all the facilities that the elevator men have. The farmer generally gets a better price by shipping to them than by letting the line elevator have the grain and also saves the margin that the elevator companies reserve. Mr. Prom has tried independent shipping, both to Minneapolis and Duluth, and it resulted profitably every time. (796.)

Mr. BUDGE testifies that the commission men in Minneapolis get 1 cent a bushel and at Duluth one-half cent on wheat. (855.)

Mr. JUMPER, of South Dakota, says the principal complaint among the farmers there is that the elevators do not pay what they should for good wheat. If a farmer has a good grade of wheat he will make money by shipping it. In many cases farmers have made from \$40 to \$50 or even \$60 a car by shipping their own wheat to Minneapolis. Some of these shipments have been made on rising markets, the market advanced 2 or 3 cents while the car was in transit, and including the margins which the elevators take, the shippers got 5 or 6 cents more than the card price; or, if he had a very good grade of wheat, all of one kind, a cent or possibly a cent and a half more. These instances are always reported in the papers, but if a shipper happened to strike a falling market the incident would not go into the papers. (737, 738.)

Mr. Jumper does not know of any instances where farmers have attempted to ship their low-grade wheat. They put it right on the market as soon as possible. Ordinarily the prices of Nos. 1, 2, and 3 are not far apart. At the date of Mr. Jumper's testimony, January, 1901, the card price of No. 3 was 10 cents below No. 2, but some farmers would get 5 or 6 cents higher than the card price, because the wheat, while grading No. 3, was fairly good quality. (739.)

Mr. Jumper says there have sometimes been car famines, but he never knew a time when an independent shipper or farmer could not get a car just as easily as an elevator. (737.)

Mr. PRATT, of Aberdeen, S. Dak., thinks there are no obstacles placed in the way of the farmer who wishes to ship his grain individually. He can load it into the car, but he has to handle it by hand; he can not load by machinery as an elevator can. The railroad companies are anxious to keep their rolling stock out of the way and not have a blockade, and sometimes the elevator that can load the cars quickly may be favored with cars as against individual shippers, but not as a rule. (725, 728.)

Mr. BUDGE, of Grand Forks, N. Dak., says the millers determine the difference in price between No. 1 and No. 2 wheat. The difference is $1\frac{1}{2}$ or 2 cents; in the case of No. 3 the difference is probably 4 or 5 cents. A farmer who has a superior quality of wheat gets the price for No. 1 hard. If a farmer has the best wheat in the market there is some advantage of his shipping to Minneapolis on his own account; he gets fairer treatment at the terminal point. If the miller thinks the wheat is above grade and wants it badly he will pay a little above the grade price for it. (854, 855.)

Mr. Budge says the farmers have equal privileges with the elevators in getting cars. He thinks there is no disposition on the part of the railroads to favor the elevator companies if they can help it. The farmer who loads his own grain saves the 2 cents that would otherwise go to the local elevator. Mr. Budge says that wherever 2 railroads come together, while the rates are no better, shippers are more apt to get cars. (853, 854.)

Mr. Budge testifies that a good many of the farmers store at the local elevators. Some of the elevators will occasionally give a farmer a special bin for use in loading in and shipping out, but sometimes they have not the bin to spare. (855.)

Mr. HANLEY says grain from the home of No. 1 Northern, which can be preserved intact and removed in bulk to Buffalo and New York, commands a premium of from 3 to 7 cents on account of its superiority. The bonanza farmers avoid the combinations of local elevators, and escape much of the loss sustained by other farmers because they can ship direct. (279.)

22. State regulation.—Mr. MORAN says the Minnesota law regulating warehouses, like many other laws, is a dead letter. The law permits the keeper of a public warehouse to buy grain. (719.)

Mr. PROM says the North Dakota railroad commission has no power over the appointment of inspectors, or the making of rules and regulations concerning storage. (799.)

23. Proposed legislation.—Mr. M. F. GREELEY, Secretary of the Board of Regents of Education of South Dakota, would make it a crime to do the kind of business the elevators do, and make the punishment so quick and so severe that it would not be done a second time. He would have the matter regulated by Congress. He adds that the farmers could regulate the "combine" if they could build and operate their own elevators and have equal shipping facilities. (943.)

Mr. Greeley wishes that the farmers might be at perfect liberty to build elevators, and buy and ship grain as they wish to. The intelligent Western landowner only asks that he be not handicapped in the race with capital. (940.)

Mr. MORAN, president of the National Grain Growers' Cooperative Association, advocates legislation placing terminal elevators under the control of the Government, through the appointment of an inspector to have charge of public warehouses and prevent public warehousemen from trafficking in or mixing grain, or from keeping the better qualities of their customers' grain and delivering the poorest grades. Mr. Moran thinks that the manager of a terminal elevator should not be permitted to buy grain, and he says his organization will ask for legislation to that effect. Mr. Moran declares that legislation that would prevent combination in restraint of commerce and trade would be a great boon to the farming community. (718, 719.)

Interstate grain inspection.—Mr. PROM believes that the office of inspector should be taken out of the hands of the governor of Minnesota, and that the inspector should be appointed for fitness and allowed to appoint his own deputies. As a more thoroughgoing remedy he proposes a system of interstate inspection established by the 4 States of North and South Dakota, Minnesota, and Wisconsin. (801.)

National grade for grain.—Mr. HANLEY says the manipulation of grain is the source of the greatest profit to those engaged in the business. He believes that if a national grade could be established and the grain bought and sold at a premium or discount with that grade as a basis, the farmer would have a chance to get some of the profit which he should have. (280.)

B. The Chicago elevator system.—1. History.—Mr. HILL, a commission merchant of Chicago, says Chicago is the greatest grain market of the world, the receipts of grain in 1898 being 320,000,000 bushels. As the Western roads brought grain to Chicago, and as their grain business increased, they all, or nearly all, built elevators in Chicago. The first elevators were built in the fifties, or possibly there was one as early as 1848. In 1870 the State of Illinois found it necessary to control the elevators to protect the grain interests of the State, and the constitutional convention of that year devoted an article of the constitution to instructions to the legislature in regard to making laws regulating the inspection and storage of grain, to be liberally construed in the interest of producers and shippers. Following the instructions of the constitution the legislature of 1871 enacted the railroad and warehouse law. From 1871 to 1887 there was very little difficulty in the handling of grain in these elevators, which were managed by disinterested parties engaged solely in the warehouse business. The rate of storage was fixed at the beginning of each year, and was the same to all persons. Thousands of buyers and sellers were brought together daily, the competition of buyers sustained prices, and that influence was felt the world over. For years Chicago was the best market for the West to send grain to.

During the few years following the enactment of the interstate commerce law, between 1887 and 1892, the method of handling grain in the elevators changed. The elevators passed out of the hands of those who devoted their entire time to the warehouse business and into the hands of persons who immediately embarked in the grain business. By the end of 1890 nearly every railroad terminating in Chicago had a favored elevator system under its protection to which were given concessions enabling it to control the grain business on that road.

Mr. Hill submits lists of stockholders of various elevator companies, showing that the officers and directors of the railroads are among the original stockholders in the elevator companies. He says the Armour Elevator Company now controls all the

CCXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

public storage on the St. Paul and the Chicago, Burlington and Quincy railroads, those on the latter road having been leased by the elevator company from the railroad and reduced from public to private warehouses for the use of Armour & Co., with the exception of one house of 800,000 bushels' capacity. The Illinois Central Railroad leases its terminal elevators to Carrington, Hannah & Co., a grain-shipping firm which owns stock in the Central Elevator Company and controls all the grain coming into these public elevators. Recently the firm has made one of the Illinois Central elevators a private house, barring out the public. The Santa Fe elevator is no longer a public house, being leased to the Richardson Company. The Rock Island elevators have passed into the hands of Charles Counselman, and one of them is being used as a private house. The proprietors of these public warehouses are the most extensive dealers in grain on the various roads, and own a very large part or all of the grain stored in their elevators. (295-297, 313.)

Mr. Hill adds that this state of affairs has gradually driven the public out of the public warehouses, as the public can not successfully compete with the elevator people, who, if they pay storage at all, pay it to themselves. The effect has been that grain of a grade that would of necessity go to an elevator, coming to Chicago on any road where these conditions exist, finds but one buyer, the elevator proprietor. (295, 297.)

2. Elevator capacity of Chicago.—Mr. S. H. GREELEY, a commission merchant of Chicago, testifies that the public and private elevator capacity of Chicago is probably over 60,000,000 bushels. He estimates that the capacity of elevators which are advertised as public is in the neighborhood of 20,000,000 bushels. The public elevators are decreasing in number; some of the railroads are assuming the position that they will furnish no facilities for the public. (229, 233.)

Mr. HILL quotes the Chicago Chronicle of August 12, 1895, as saying that over 20 per cent of the whole storage capacity of the United States and Canada is located at Chicago, Duluth having a capacity of 27,200,000 bushels; Minneapolis, 26,000,000 bushels; St. Louis, 13,350,000 bushels; Milwaukee, 5,430,000 bushels, and Toledo, 7,200,000 bushels; a total of 125,830,000, or about five-eighths of the whole. (314.)

3. Combined action of warehousemen.—Mr. BRIGHAM believes that there are combinations among the elevator and warehouse owners. Elevators along the same lines of railway are believed to have an agreement as to prices. Practically all grain must pass through Chicago, and the warehousemen there have an opportunity to demand whatever charges they will. (24.)

Mr. HILL says it was discovered in 1894 that there was an association composed of all the elevator people in Chicago. When the Board of Trade found it necessary to treat with the elevator people it was all done through this association; it was not possible to treat with one of the elevator proprietors separately. It was found that the elevators always had the same rates of storage and that they were represented at all times by the same attorneys. (309, 310.)

4. Storage charges.—Mr. RICHARDS and Mr. S. H. GREELEY agree that the charge for storing grain has been reduced to three-fourths of a cent a bushel for the first 10 days, and one-fourth of a cent for each 10 days thereafter, and that there is money in the storage business at these rates. (216, 234.)

Mr. HILL, in a statement before the Illinois legislature in 1897, said that the charge of three-fourths of a cent a bushel for the first term of storage was retained only as a protection to the elevator managers against the competition of legitimate dealers. The public could not avoid it, but it was ignored by the elevator managers in their own transactions, thus forcing everyone to sell to or buy from them. The charge, not being bona fide but only a foil to competition, should be abolished. (314.)

Mr. Hill quotes with approval an article in the Chicago Chronicle of September 6, 1895, to the effect that the Chicago storage rate of one-fourth of a cent a bushel for each ten days means for all the empty bins \$450,000 a month, or \$5,300,000 a year. These figures were said to explain the anxiety of the Chicago elevator trust in combination with the Northwestern elevator interests to depress wheat prices in order to earn money with their idle warehouse room, and profit by buying wheat for future delivery. (316.)

5. Short weights.—Mr. RICHARDS says there are about 28 or 30 terminal elevators in Chicago, supposed to be public warehouses, but not one is run in the interests of the people. They are all run by about 7 or 8 firms. Mr. Richards thinks there is no pooling among these firms, but that there is an understanding as to what the rates of storage shall be and as to other details of the business. The elevator people have their buyers out in the country, and send out quotations every day. Whenever a firm sells to one of these country shippers, he sells subject to Chicago weights and inspection. If he falls short 2, 3, 5, or 10 cents a bushel in Chicago, he has no remedy. His bill of lading over the railroad will not protect him because it says "sub-

ject to loss in weight." If the weight overruns, that is one of the perquisites of the shipper's business. There has been very serious complaint about the weights falling short, and in regard to the inspection. (202, 203.)

6. Mixing of grain.—Mr. HILL testifies that the mixing of grain is so important a matter that every terminal elevator in Chicago, with possibly one or two exceptions, has a mixing house connected with it. The Armour mixing houses are larger than their public houses. Grain of high quality is then run through the cleaning house and a lower grade of grain is mixed with it to bring it down to the lowest point at which it will go in the same grade as before. This fixes the price of wheat injuriously to the farmer, and affects the price at terminal points, because grain sold by sample for export is sold at a premium over the speculative grade held in store at Chicago. No farmer gets the benefit of the premium; the only one who does is the man who mixes the grain and sells it. The premium varies from 1 to 3 or 4 cents a bushel. (319.)

7. Manipulation of grades.—Mr. RICHARDS says the public suffers great injustice from the elevator system of Chicago. Chicago has an elevator capacity of about 40,000,000 bushels, but there is not a public warehouse or an elevator run in the interests of the people. The warehousemen deal in grain, and the grades are so manipulated that it is hard to tell what one is getting in buying wheat. If one wants to get a special quality of grain, he has to pay a premium on it; he can not get it in the open market. If wheat weighs 56 pounds to the bushel and is reasonably clean, it will grade No. 2; if it weighs 63 pounds it will also grade No. 2, though there is a difference in its value to the miller of 5 to 10 cents a bushel. A warehouseman can take 2 cars of No. 2 wheat and 3 cars of No. 3 wheat, the difference in value ranging as high as 15 cents a bushel, and make 5 cars of No. 2 wheat. The dealer does not always get back the same kind of grain he puts into the elevator. As a remedy for this evil Mr. Richards suggests the sif of grain by sample. (202, 205.)

Mr. GREELEY says the temptation put into the hands of men conducting public warehouses has led to some of the most gigantic robberies known in commercial life, at the expense of general trade. He believes there is a continual underhanded business on the part of at least some of the warehousemen, that they manipulate the grades and weights and attempt to manipulate the inspection. He does not believe it possible for a man to be custodian of the people's property and of his own without great temptations of this kind. (232, 233.)

Mr. HILL introduces in his testimony a letter from the Nash-Wright Company, of Chicago, to illustrate the methods employed toward country elevators by public warehousemen of Chicago when dealing in grain. The letter states that a warehouseman operating both public warehouses and cleaning houses received 50 cars of No. 2 corn. He called for reinspection and asked that the shipment be changed to Nos. 3 and 4, which would have lessened the market value from 2 to 5 cents a bushel. The supervising inspector said that the corn was of the best quality coming into Chicago. The writer of the letter infers that the corn had been bought from shippers in the country, and that the aim of the dealer was to secure it at heavy discount, then run it into the cleaning house and have it inspected out as No. 2 corn. (318.)

8. Elevator premiums.—Mr. HILL quotes and indorses an article in the Chicago Chronicle of August 22, 1895, declaring that one of the great weakening factors at that time was the attitude of the warehouse interest in insisting on premiums on every bushel of wheat sold. Within the year premiums of from 2 to 3 cents for winter wheat and 6 to 7 cents for spring wheat have been asked and received by the elevator men, and at no time within the year had it been possible to buy wheat in the Chicago market except at a premium. If the market were allowed to resume a normal condition and prices were permitted to remain on a par with futures, much more wheat could be sold to foreigners, who "will not submit to be bled by a grinding monopoly." The premium charges not only curtail exports, but also depress prices by keeping grain at accumulative centers. In the presence of plenty, buyers look at the premium as an extortion, and naturally refrain as far as possible from paying it. By curtailing exports, the premiums charged were responsible in large measure for the exportation of gold and its deleterious effects. (316.)

9. Fraudulent warehouse receipts.—Mr. HILL states that on May 1, 1896, Armour & Co. delivered to members of the Board of Trade fraudulent warehouse receipts for 1,200,000 bushels of wheat. The magnitude of the swindle attracted attention, and the directory investigated the matter and voted the entire Armour system of elevators irregular. The directory also caused a committee to investigate the members of the board responsible for the fraud, and the committee, after investigation, filed charges against 4 members, 3 of whom denied knowledge of issuing the receipts, while the fourth, who assumed the responsibility, was convicted and suspended from the board for 20 years. It was shown during the trial and investigation that warehouse receipts to the amount of about 12,000,000 bushels had been manipulated in

COCCXX THE INDUSTRIAL COMMISSION:—AGRICULTURE.

this way, beginning with the Cudahy wheat deal in 1893. Thus for 3 years the public and members of the Board of Trade had been systematically plundered, and the market depressed by the delivery of undesirable warehouse receipts which expired the day they were delivered and were dated months after the grain was received in the elevator. Dates were so manipulated as to induce shippers to take the grain out of store. (317, 318.)

10. Relations of railroads to elevators.—Mr. S. H. GREELEY, a commission merchant of Chicago, thinks the railroads formerly extended rebates to individual shippers to bring grain to the Chicago market; but the interstate-commerce law made it necessary, in their opinion, to put the rebate in the hands of favored individuals whom they could trust. They chose for that purpose the public warehouseman as the party with whom the lowest rebate would serve their purpose. They gave him an elevator on the right of way, and favored him with facilities to compete with the public in drawing the grain from the West to Chicago. These advantages he still receives. The public warehouseman was appointed a secret rate getter or secret facility man. His advantages in competition with the public are (1) that he pays no storage on grain, or if he pays storage he pays it to himself, so that possession of the elevator operates as a rebate to that extent, and (2) that he is able to select the best grain of a certain grade and keep it for himself as merchandiser, giving the public a line grade, or a grade just good enough to pass inspection, and thus keeping the public at a disadvantage. These two points are of such importance that the shipping interest from Chicago to the East on the part of the public is dead. They have also reflected upon the receiving interest from the West. To-day there is practically one set of buyers on the Chicago market, each railroad having a man with these facilities. This not only kills the competition for grain in the West, but also kills the competition in the sale of grain to Eastern markets and for export, and has a very important effect on the values of grain. (227, 228.)

Mr. Greeley is of the opinion that these facilities are given to public warehousemen by the railroad companies to protect the latter from grain being attracted from what they consider their legitimate territory to other points. The system of through billing and other matters have combined to make it necessary from their standpoint to protect themselves. It is almost impossible to conduct the grain business on the Western railroads properly without special rates to give the railroads their proper haul. (229.)

Mr. Greeley says he has an indefinite amount of evidence leading him to believe that the railroad-officials and warehousemen of Chicago are very close together. The more the railroads drive out competition, the better they seem to like it, and the public is treated with the utmost indifference. Mr. Greeley does not believe it will be possible to have general competition in any commodity as long as it is possible for the railroad official to divide the rebate with the man to whom he gives warehouse facilities. (231.)

Mr. Greeley believes that the railroads want the business on their lines done by favored parties; that the stockholders suffer and the officials divide the "swag." (233.)

Mr. RICHARDS says the elevators of Chicago, with a few exceptions, are owned by the railroads. He is informed that they are leased under an arrangement that the lessees shall pay so much a car for all grain going through the elevators. He thinks it is generally believed that the lessees get special favors in the way of rebates or concessions that do not belong to them. When a railroad company ships a carload of grain, it makes out besides the waybill an expense bill showing the freight charge to Chicago, which is paid by the Chicago consignee. The rebates are managed by means of these expense bills. An elevator man first pays the regular tariff; at the end of the month he makes up a statement of the amount of grain he has received and sends it to the railroad company. The rebate is figured out, and is not paid out of the freight department, but is charged up to some other fund; it may be the bridge fund, the repair fund, the passenger fund, or some other. (203, 204.)

11. Evils of speculation by warehousemen.—Mr. HILL, in a statement before the Illinois legislature in 1897, defined the natural function of warehousing to be accepting for storage the overflow of the season of freest movement, that the channels of commerce may not be clogged, and caring for it while awaiting demand. The alliance between the railroads and the elevators, he said, had resulted in reaching out after millions of bushels of grain not naturally tributary to the Chicago market, and then preventing it from getting away as long as storage could be collected on it. The accumulation and storage of grain had come to be the chief aim of dominating forces in Chicago, resulting in such a congestion of grain as to depress prices to the lowest point in history. The volume of the Chicago stocks invited dealers in every market in the world to make sales there against holdings elsewhere, which they

would not dare to do but for the abnormal accumulations held there. Cargoes of wheat bought on European account in Australia, India, Russia, and Argentina, and stocks at all other points of accumulation were sold against in Chicago, so that the Chicago market felt the weight of the entire world's surplus. This condition was made possible by the enormous hoard retained in Chicago to satisfy the avarice of half a dozen corporations, the largest of which was owned in London, and which, "by the rankest and most brazen manipulation," sought to control the price and movement of commodities. Mr. Hill charges that the elevator men were able to set aside and sell at a premium every year millions of bushels not owned by them, but in their custody as warehousemen. In the spring of 1895, when the quality of millions of bushels of grain stored in public warehouses was asspersed by interested speculators, the Board of Trade sought to have an investigation made, but every elevator proprietor in Chicago joined in refusing to let the committee of experts make this examination. They knew the grain was above the average in quality and condition, but were willing to have it suspected in order to increase carrying charges.

Mr. Hill declared a system permitting the proprietors of public elevators to deal directly or indirectly in the property of which they are custodians to be essentially immoral, and said that the principal motive of the warehouse law was to prevent their ownership or control of grain therein, yet they had within a few years sold millions of bushels from public elevators by sample at a large premium, not a cent of which in equity belonged to them. The grain bought by the elevator proprietors is promptly sold for future delivery, so they become custodians of other people's property, which, however, the public can get only on the payment of a premium.

Each railroad terminating in Chicago was declared to be controlled practically by a single buyer—favored individuals having the advantage of special rates and of elevator control—so that the rates charged to the public were rebated to themselves, enabling them to outbid or undersell all competitors. The elevator monopoly was characterized as a "blight on legitimate business," threatening the existence of all competition. In reply to the claim of the elevators that their bringing grain in large amounts to Chicago furnished employment to banking capital and kept up the rate of interest and gave business to railroads and insurance companies, Mr. Hill replied that half a dozen firms and corporations had a monopoly of the business and that they could not force to Chicago grain not naturally tributary thereto except by cut freight rates forbidden by law, while if they were prevented from dealing in grain each railroad would have a host of competing patrons instead of one; bankers would have thousands of active accounts instead of a small group of large borrowers able to combine and dictate rates, and the short-rate card of insurance offices would again come into use. (312-314.)

Mr. S. H. GREELEY testifies that the Chicago warehousemen are not custodians appointed by the State, which was the original intention of the State law and constitution, but override the law and become merchandisers. As soon as warehousemen get possession of grain, they jump into a pit and sell it ahead for future delivery and make a hedge; then some one else is carrying the grain and paying storage charges. (233, 234.)

Mr. Greeley says that the public warehouseman carries grain in his warehouse to accumulate storage charges. His object is to get possession of it and sell it ahead for future delivery, which he can do at a lower price than another man, who would have to pay the regular storage rates. The warehouseman waits for the buyer to sell out, and stands ready to take the grain from him and sell it ahead for another deferred delivery, and thus accumulate another storage charge. This has produced an endless chain of forced liquidation on the part of buyers in the Chicago market. The warehousemen not only carry the grain for storage, but so manipulate the grades by reducing the quality to the line grade that the man who buys it for future delivery does not want it as a merchantable commodity, and sells it back to the warehouseman, thus continuing its life in storage and the tax on the public. Chicago probably has in public and private warehouses a capacity of more than 60,000,000 bushels, the larger proportion of which Mr. Greeley believes is operated so as to make the storage charges out of the speculative public. In 1898 Chicago handled 300,000,000 bushels and more, or nearly 300,000 carloads of grain, a large proportion of which passed through the public warehouses. (227-229.)

Mr. Greeley says a public warehouseman has no more right to deal in grain in competition with the public, with the privilege of mixing his grain and paying no storage, than the collector of the port of New York has to deal in tea, coffee, or silk in competition with merchants and pay no import duty. (231.)

Effect on prices.—Mr. GREELEY says this system puts the control of the market into the hands of those who hoard this vast amount of grain, and the lower they can get the prices the more money they can make, because insurance and interest are

CCCCXXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

reduced. There is not enough trade in the speculative grain market to carry the market against the current produced. Mr. Greeley believes that this was one of the important conditions which led up to the panic of 1893, by reducing the value of grain so that people repudiated their debts. He admits that the public warehousemen are able to pay more than the others to the farmers to get possession of the grain, but says they hoard it, and take from 5 to 10 or 20 cents a bushel off the entire crop. They pay a cent a bushel more in Nebraska than in Iowa, to get possession of the far Western grain which is likely to go somewhere else. Mr. Greeley believes that there is collusion between the different elevator companies. Five of the warehousemen come together every day and make a price that is sent out to the grain trade. (229, 231, 233.)

Mr. Greeley believes that the prices of the grain crops of the world are largely made on the Chicago Board of Trade, and largely controlled through the influence of one man. The foreign demand is a factor, but the Chicago market may be depressed in the face of an encouraging demand. The Liverpool market has little to do with the price of December corn in August. A rise in the price of wheat on the Chicago Board of Trade generally calls out a new army of short sellers who weigh the prices down again. (234, 235.)

Mr. Greeley says the man who is injured most by this elevator system is the one who raises the grain. In a free, open market without these hoards of grain, values would be 15 to 25 per cent higher. In proof of this he adduces the low prices of grain as compared with former years. (234.)

Mr. RICHARDS says there is a little coterie in Chicago that fixes the prices of grain, arbitrarily manipulating the market to suit its own purposes. He thinks the price in Liverpool or New York no longer cuts any figure. The Chicago elevators have 40,000,000 bushels capacity, and sometimes are pretty full. When there is a large accumulation of stock of any commodity the tendency is to depreciate the price. These elevator men can create a glut at any time, and the more grain they have the more they can make out of the storage charges. Formerly country shippers would send their grain to the commission merchant, and the price would be determined after the grain arrived, being governed largely by the receipts and shipments, but these legitimate influences appear to have become obsolete. Mr. Richards thinks the producer would be benefited if he could send his grain to an open market, where it could be sold subject to the laws of trade. (215, 216.)

12. Monopoly in grain.—Mr. HILL quotes and indorses an article from the Chicago Chronicle of September 7, 1895, declaring that the wheat trade was practically in the hands of a grain monopoly—the elevator interest—which was manipulating the market, seriously crippling the trade, holding down prices, absolutely preventing shippers from filling legitimate orders, and driving trade away from Chicago. A shipper had been compelled to pay the December price, or a premium of over $1\frac{1}{2}$ cents a bushel, for a small lot of wheat. There was practically no wheat for sale in Chicago, though there were some 14,000,000 bushels in store there, all owned by the elevator trust. (316, 317.)

Mr. Hill quotes with approval an article published in the Chicago Chronicle in August, 1895, to the following effect: The elevator proprietors are large speculators and own about 80 per cent of all grain stored at Chicago. In 1894 they sent buyers into the country and brought large amounts to Chicago solely for the purpose of making it earn them storage. This move was very injurious to the country, because it swelled the visible supplies, especially of wheat, to such an extent "that the world, being unacquainted with the real cause thereof, stood aghast and insisted on lower prices, arguing, quite naturally, that America had an enormous plethora."

It also took from the regular receivers at that point a large share of the business which would have come to them under ordinary conditions, and practically threw the grain trade under the control of the elevator interests, who become arbiters of prices and could widen out or contract the "spreads" between one month and another for their own ends. The July-September spread (the difference in price between July and September wheat) was run up to $2\frac{1}{2}$ cents early in July, 1895, when the real carrying charges were only $1\frac{1}{2}$ cents. On July 1 some 5,000,000 bushels of wheat were delivered on July contracts, mainly by the elevator proprietors. The article implies that this was done for the purpose of breaking the market, so that wheat could be bought more cheaply, and that elevator men sell long options freely to break the price, and then buy near options at a relative decline, replacing that sold at a profit. Under the methods in vogue the opportunities of elevator men for making money are declared to be enormous, and the result is said to be practically killing off business in Chicago, as the outside world prefers to go to some market not at the mercy of such a combination. (315.)

Mr. RICHARDS says that Chicago, by reason of its commanding geographical position, would naturally be a very strong point under favorable conditions, but the elevator system "got tangled up," the Chicago grain dealers have lost their grip, and the grain is going around them. Boston dealers get their grain in Iowa instead of in Chicago. Mr. Richards is inclined to think that the amount of grain shipped from Chicago is lessening every year. (202, 211.)

Mr. S. H. GREELEY predicts that the time is not very far distant when there will be no general competition in grain, when prices will be fixed by railroads or favored men, when speculation will be killed as speculation in oil was, and the Chicago Board of Trade destroyed and the building sold to protect the bondholders. (235.)

13. Espionage over the business of other dealers.—Mr. HILL submits copies of letters addressed by a number of Chicago receivers and shippers of grain and flaxseed to the Illinois Central, Chicago, Rock Island and Pacific, and Chicago, Burlington and Quincy railroads, demanding that the roads furnish terminal facilities for the handling of grain and flaxseed at Chicago that would not subject their business to the scrutiny of their competitors. It was stated that grain and flaxseed unloaded in the terminal elevators of these 3 railroads passed into the possession, respectively, of the Central Elevator Company, a corporation owned entirely by Carrington, Hannah & Co., Charles Counselman & Co., or A. C. Davis & Co., and the Armour Elevator Company, or virtually Armour & Co.; that Carrington, Hannah & Co., Charles Counselman & Co., A. C. Davis & Co., and Armour & Co. were active competitors of the petitioners; that they were enabled to exercise a complete espionage over the latter's business, had the opportunity of selecting the best grain of the various grades to fill their own orders, and that the railroads, by leasing their terminal elevators to these firms, created for them a margin, practically giving them a monopoly of the grain and flaxseed trade on their lines, the storage rate in itself being so great an advantage that the lessees frequently sacrificed a portion of it in order to force grain and flaxseed into the elevators so that it would earn storage. They would buy at what would be a loss to other dealers, and yet make money, because of the superior advantages provided for them.

To these letters the Central Elevator Company replied that it was required by the directors of the Board of Trade to furnish a bond of \$500,000 to protect the members who handled the company's receipts, and that the insinuation that the elevator company, or Carrington, Hannah & Co. took advantage of the situation to spy out the customers of competitors was "unworthy of the notice of honorable men;" that the identity of the grain and flax going into the elevators was not preserved, and hence that the elevator company could not know the ownership of any particular lot. The reply of the Chicago, Rock Island and Pacific Railway stated that no specific case of manipulation of grades had ever been brought to the attention of the officials, and that specific complaints of that character would be investigated at any time. The reply of the Chicago, Burlington and Quincy Railroad stated that the road stood ready to deliver grain to any elevators in the city, subject only to such extra charge as might be exacted by the lines on which the elevators were located. (304-308.)

Mr. RICHARDS says the business of the Illinois Grain Dealers' Association is also subjected to the inspection of their competitors of the Class A elevators. (204.)

14. Other abuses in the Chicago grain market.—Mr. S. H. GREELEY, a commission merchant of Chicago, says that the natural supply and demand no longer control prices in the Chicago grain market, but that values are controlled by an artificial organization, including 4 or 5 distinct systems: (1) The railroads, (2) public warehouses, (3) speculation, (4) bucket shops, and perhaps (5) the ownership of private cars by individual firms operating through railroad companies. (227.)

Bucket shops.—Mr. GREELEY defines a bucket shop as a place where people can go for the supposed purpose of buying and selling grain, but which in reality is a place in which a bet is made with the proprietor as to whether the price will go up or down. Mr. Greeley estimates that from 75 to 90 per cent of the outside trade in the bucket shops is buying on the part of the customers, but this fictitious buying does not influence values. He believes the bucket shops are successful as profit-making institutions, and that their success means depression of the price. The storage privilege granted by the railroad companies to public warehousemen operates to the detriment of purchasers both in the bucket shop and on the Board of Trade, and thus indirectly the railroad companies are largely responsible for the success and existence of bucket shops. If this large stock of grain did not exist, the bucket-shop proprietor would be subject to natural market conditions and take as many chances as the buyer, there would be more frequent rallies, the short side would be unsatisfactory, and the bucket shop would be pushed out of business. (230.)

Bear speculators.—Another very serious menace to the producer born of the public warehouse system, according to Mr. GREELEY, is the professional bear speculator,

OOOXXXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

who is encouraged in the same way as the bucket-shop proprietor. The system operates in favor of the short seller, making a bad condition in the market, notwithstanding the general business prosperity that would naturally put the price of grain from 10 to 20 cents a bushel higher. On the Board of Trade the professional raider and the warehouseman are against the outside buyers. (230, 231.)

As showing the influence that can be brought to bear by the speculators on futures, regardless of supply and demand, Mr. Greeley testifies (August, 1899) that September corn commands a heavy premium over far-away futures, and cash grain a premium over September; and that very poor grades sell on a par with the best grades on account of the demand. (235.)

Illegal bills of lading.—Mr. RICHARDS says the bills of lading issued by the transportation lines for grain do not comply with the statute of Illinois requiring that grain received for transportation shall be carefully and correctly weighed and a bill of lading issued stating the true weight, and requiring the company to deliver to the consignee the full amount of the grain without deduction for leakage, shrinkage, or other loss in quantity. The weight is put in a column headed "Weight subject to correction," or some bills of lading read, "Said to contain" so many pounds. In many cases facilities do not exist for weighing grain properly at the initial points. There are some country stations at which the farmers have to weigh the grain on the wagon scale of the shipper and then shovel it from the wagon into the car; the sum of these weights is inserted in the bill of lading as an approximation, but the bill of lading is merely a memorandum; the railroad does not assume to know what the weight is until the grain reaches a point of transfer. In a majority of cases the weights are determined in Chicago, and the shipper must accept the railroad's statement as final. Mr. Richards's experience has been that there has been a shortage on an average of 3 or 4 bushels to the car. The shortage has gone as high as 100 bushels; it is not uncommon to have it 20 or 25 bushels. The average shortage when grain is honestly weighed out and weighed in is only about 30 pounds to the car. Mr. Richards says the shippers never institute legal proceedings to protect their rights, because it costs money and time and aggravates the railroads. A man who is shipping grain is very careful not to provoke the railroads; he has to keep good-humored or he will get into trouble. (212-214.)

Mr. Richards says these bills of lading are illegal, and in many cases are used to conceal fraud. Millions of dollars are lost annually to owners and shippers by reason of defective bills of lading and other illegal methods employed by agencies between the producer and consumer. This can be stopped only by national legislation. (207.)

Ownership of private cars.—Mr. S. H. GREELEY condemns the growing system of the ownership of private cars by individuals and corporations. He believes there is one man in Chicago who owns between 10,000 and 20,000 private cars, so that he can lose money in merchandising and still get enormous profits from the railroad companies on account of this special facility granted him. The public is out of business in anything this man attempts to deal in. (231.)

15. Report of the Board of Trade committee.—Mr. HILL introduces in his testimony a report made April 30, 1894, by a committee of the Chicago Board of Trade appointed to investigate warehousing methods, which spent several weeks in the investigation and took testimony from probably 75 witnesses. The committee said:

"We find that the regular elevators of Chicago are owned and operated in a variety of ways. One system is owned by an individual, who does all the business—buying, selling, and storage—in his own name. Another is partly leased by an individual and partly owned by a corporation, all of whose stock is owned by this same person. Here all the business is done in the firm name, and the accounts are simply kept separate on the books. Another system is leased by a corporation whose stock is all owned by the firm who operates it and which does its own grain business largely through them. Several systems are owned or leased by corporations which do all their business in their own name. A large system is owned by a foreign corporation, which employs commission houses to do its buying and selling. The largest system in the city is leased by a corporation of \$100,000 capital whose ownership is not given. The private elevator or cleaning house connected with this system is owned by another corporation. Here the grain business is all done in the name of the firm who are generally supposed to control both corporations.

"Five systems, with about 19,000,000 bushels of storage capacity, have private elevators or cleaning houses connected with them, while 6 systems, with 13,000,000 bushels storage, have no cleaning houses connected. All of them buy grain, directly or indirectly, both here on our own board and also in the country. Some of them sell their grain exclusively on the open market or to our own shippers, while several sell in the East or ship on their own account as well.

"The necessity for grain buying by these elevator proprietors is hardly well established by their own testimony. All but one claim that they pay only the market price, giving no part of their storage to the seller, while the proprietor of one system claims that possibly 40 per cent of his grain would not come to Chicago unless he bought it. It is but fair to say that this scale of prices claimed to be paid by the elevator system is contradicted by at least one firm, who are large receivers and shippers. They testify that they find it at times to their advantage to sell their own grain to the elevators and buy their cargoes back from them. In addition, the receivers generally testify that they can get more for grain to go to store than they can get for the same grain if already in store."

The committee declared that the fact that public custodians handling the property of hundreds of individuals and mixing it regardless of ownership should themselves be

the principal dealers in the same property was, "to say the least, anomalous." It was not found that the railroad and warehouse law prohibited this directly, but the committee thought the spirit of the law was fairly against the practice. The combination of the 2 occupations of dealer and custodian, with the unfair advantages accruing from the latter position, were believed to be against public policy. The following advantages were specified: (1) The opportunity to contaminate the inspection department and improperly influence the railroads; (2) the opportunity to tamper with grain, selecting the better qualities of a grade for themselves to sell by sample in other markets, thus reducing the average quality of the public grain, and the danger of surreptitiously working off their own inferior grades; (3) the use of the public storage rate in their own interest in the buying and selling of grain to the injury of the general trade.

The committee doubted the propriety of making "regular" any elevators having private elevators or cleaning houses connected with them or under the same ownership or management, arguing that the paramount interest of the owner of a public elevator should be to maintain the integrity of the standard grades of grain, and that when running a cleaning house his constant endeavor was to pass his own grain on the lowest line of the grade.

The committee found that it was the practice of the inspection department, when the quality of grain was objected to by the shipper and the objection sustained, to permit the grain to be taken back at the same grade at which it was wrongfully inspected; also that the inspection department exercised no supervision over grain while in the elevators, but simply inspected grain in and out. While the inspection was under the supervision of the Board of Trade and in the earlier days of State grain inspection, there was in every elevator a distributing inspector, who directed into which bin every car of grain was to be run, and when grain was to be shipped from which bin it should be drawn, and who saw that the oldest grain in the house was shipped first.

The committee found that some elevator proprietors who were in the habit of putting the more desirable qualities of their own grain in bins marked "special" were not equally careful to mark the receipts for these special bins as required by law. The committee did not find that the grain registrar took any special cognizance of this special bin grain or the receipts issued therefor.

The committee found that grain was being held in Chicago too long for its own good or for the good of the trade, as a result of the holding of grain for storage purposes and the concentration of speculative trading into 4 months of the year. The amount of wheat in store at the date of the report was nearly 20,000,000 bushels, a large proportion of which had been in the elevators more than 12 months. Shippers could get grain to fill their orders only by paying a premium. (310-312.)

The committee made the following specific recommendations: (1) An amendment to the law strictly prohibiting the proprietors of warehouses of Class A from being directly or indirectly engaged in the grain business; (2) that the attention of the Railroad and Warehouse Commissioners be called to the practice of the inspection department in permitting degraded grain to go back into the same bins, and an attempt made to have it stopped; (3) that the Railroad and Warehouse Commissioners be asked to have a distributing inspector placed in every warehouse; (4) that the board be asked to direct the grain registrar to attend to the grain in special bins and the corresponding receipts; (5) that the Board of Trade make receipts for grain in special bins irregular for delivery on contracts, as elevator proprietors keeping their property in shape to sell by sample at a premium should not have the protection of the public elevator and the open market to protect them against unprofitable hedging sales; (6) that a committee be appointed to examine every bin of wheat in the regular elevators and report the bins found out of condition or tending to become so, and that the elevator proprietors be instructed to move such grain out at once. The committee also suggested a rule limiting the age at which receipts should be regular for delivery on contract. (311, 312.)

16. *The Chicago elevator cases.*—Mr. HILL submits extracts from the decisions of Judge Tuley in the elevator cases, and from the opinion of the Supreme Court of Illinois affirming that decision. These were 9 cases brought by the Attorney-General of Illinois against the public warehousemen of Chicago. The allegations made in these cases were that the defendants had stored in their warehouses grain owned by themselves; that not less than three-fourths of all the grain received in the public warehouses of Chicago was owned by the warehousemen; that the grain of each grade was not of the same quality, but that separate carloads of different quality were included in the same grade; that by reason of the defendants' advantages as warehousemen in mixing and manipulating grain, rebating storage charges, and otherwise, they had been able to drive out competition, and that their practices were unlawful and injurious.

The relief asked for was a perpetual injunction restraining the defendants, as warehousemen, from storing grain in their own warehouses. The answers set up a general custom of 30 years' standing under which public warehousemen were accustomed to store their own grain and mix it with that of their customers, and stated that the Warehouse Commissioners had construed the act of 1871 as permitting that custom. It was also maintained that the custom had a beneficial effect upon the producer and shipper of grain. (301, 302.)

The defendants in these nine suits were all licensed as public warehousemen, and although some of the licenses included the privilege of dealing in grain, the issue was practically the same in all the cases, as licenses could not grant the privilege unless the law under which they were issued justified such dealing. The litigation involved the construction of the statute of 1871 concerning warehouses.

The great weight of the evidence was to the effect that the warehousemen of Chicago did not commence to deal in grain to any general extent until about the year 1885. Before that time the railroad regulations were such that nearly all grain received was forced to go to public warehouses, the warehouse receipts being bought and sold in the Chicago market. About that time the railroads made regulations by which grain could easily be sold on the track, a certain time being given for inspection, and 72 hours for removal, without charge for demurrage by reason of detention. By reason of the facilities offered there soon arose at Chicago and other grain-buying centers, the practice of buying grain on the track, and partly as a result of this practice, selling by sample became quite general in Chicago. There also arose during the eighties a system of through billing of grain from the initial point to points east of Chicago. The consignee, however, had the right to sell the grain on the track in Chicago, and to change the destination of the grain and the name of the ultimate consignee; or he could stop the grain in Chicago by paying the local rate to that place. The difference between the through rate and the sum of the two local rates was about 2 cents per 100 pounds, which operated to discriminate against Chicago. It also appeared that the railroads made a discrimination in freights against Chicago by which grain was diverted to St. Louis and other points. The consequence of this changed method was that much of the grain failed to go to the elevators in Chicago, and the best grain being sold by sample, only the "line grade" grain went into the warehouses. The difference in price between "line grade" and grain of the same grade sold by sample varied from 2 to 15 cents a bushel. In the meantime the storage capacity of the Chicago elevators was continually increasing. The capacity was about 26,000,000 bushels in 1885, and over 41,000,000 bushels in 1895.

There also arose in the eighties cleaning houses, where grain was taken in at one grade and came out a better grade after being cleaned and, if necessary, mixed with better grain. This profitable business came into competition with the public warehouses, and many of the owners of the latter also established and operated cleaning houses. Private warehouses also arose, and together with the cleaning houses diverted much grain from the public warehouses.

The warehousemen soon perceived that if they did not buy grain their warehouses would cease to be profitable. Their dealings in grain grew so rapidly that they became the principal buyers and sellers on the Chicago market, and practically drove out of business those who had formerly been engaged in buying and shipping grain. It was admitted that they owned at least three-quarters of all the grain in storage in the public elevators of Chicago, and it appeared that they were fast monopolizing the business. The warehouses on the different railroads were the principal, and in some cases almost the only buyers of grain on those roads. Nearly all of them dealt in futures. The warehouse proprietors would often overbid private bidders for grain on the track, offering as much as a quarter of a cent a bushel more, and then immediately resell the grain at a quarter of a cent less than they paid, requiring the buyer to take it from the warehouse within a limited number of days, and thus making the storage charge more than compensate for the loss on the sales. In other words, they used their capital in trading in grain in competition with the public.

Judge Tuley decided that the warehouse law of 1871 should not be so construed as to give the warehousemen the right to use their privileges to crush out competition in the grain business, and that their dealing in grain was ultra vires and against public policy. (298-301.)

The Supreme Court, in affirming this decision, declared that the public warehouses were public agencies and that the licensees pursued a public employment, clothed with a duty toward the public. Their practice in giving receipts to themselves as individuals, to be used in trade to build up a monopoly was declared inconsistent with the full and impartial performance of their duty to the public. The court declared that there was an entire failure to show that in general there was any result-

ing public good to producers or shippers, and decided that a public warehouseman could not be permitted to use the advantage of his position to crush out competition and establish a monopoly by which a great accumulation of grain was liable to be suddenly thrown upon the market. It was shown that the defendants were large dealers in futures on the Chicago Board of Trade, and held an enormous supply of grain ready to aid their opportunities as speculators. (302.)

17. *State legislation of 1897.*—Mr. HILL submits a letter from Mr. B. S. Tyler, secretary of the Illinois Grain Dealers' Association, and a statement made by himself as president of the Grain Receivers and Shippers' Association of Chicago before the State legislature in 1897, in opposition to a bill introduced into both houses of the legislature and said to be pushed by the grain elevator trust. The letter of Mr. Tyler stated that Judge Tuley had, on December 22, 1896, decided that public warehouses had no right to deal in grain, and that the case had been appealed to the State Supreme Court; that the elevator men, knowing that Judge Tuley's decision would be sustained, were attempting to secure the passage of the bill in question, which would give them the right to deal in grain and monopolize trade at the expense of the producers, buyers, and millers. The letter, apparently a circular, urged the recipient to join in a protest against the passage of this "nefarious bill." (317.)

Mr. Hill, in his statement before the legislature, characterized the bill as entirely in keeping with the methods of the elevator monopoly, its sole purpose being to get into the statute something that could be construed so as to permit the continuance of their evil practices. He declared that it would give no relief to producers or shippers, and would only lead to further litigation. The elevator monopoly, he said, asked to be relieved of all responsibility as warehousemen, and asked that their elevators be put under the supervision of the State grain inspection department, at a cost of about \$60,000 a year. (314.)

Mr. S. H. GREELEY believes that the legislation secured by the warehousemen at Springfield was secured by the use of money, and that this opinion is quite generally accepted by the men who were present. (233.)

18. *Transfer of grain at Chicago.*—Mr. RICHARDS, a grain merchant of Chicago, says that previous to 1884 grain was shoveled by hand from the Western cars into the Eastern cars at Chicago, the Western railroads not allowing their cars to go east of Chicago. A carload of grain was first weighed on the track scale, and the weight of the empty car afterwards deducted. There was a great deal of trouble about the weights, and claims for shortage were continually made by Eastern and Southern correspondents. The railroads remitted the freight on the difference, but refused to pay any claims for shortage. About 1884 Mr. Richards built a transfer house for the Lake Shore and Michigan Southern Railroad, by means of which the grain was taken out of the cars and weighed by the hopper system. The car was run up an incline and the grain taken out by steam shovels into the hopper scale and the net weight taken. That weight was always correct, and was accepted by the trade everywhere as satisfactory. This system is still in use in a modified form. To obviate the expense of pushing the car up the incline, Mr. Richards devised a plan for elevating the grain from the grade level; practically an elevator apparatus without storage. (201, 202.)

Mr. Richards says the law of Illinois requires grain to be weighed in hopper scales, to eliminate the inaccuracies of weighing it on track scales. This law is only partly complied with; four or five roads use the hopper system, but some do not. Five cars can be unloaded in 8 minutes by the hopper system. (214, 215.)

Mr. GREELEY has noticed that some of the Eastern roads have followed the example of the Western roads and placed their transfer houses in the possession of grain dealers. The Lake Shore road, instead of operating its transfer houses in the interest of the public, has the grain transferred by a grain dealer. If the owner of oats wishes them clipped, his competitor clips them, and if he wishes, knows the destination of every car that leaves the clipping house. The same condition exists on the Wabash and Pennsylvania lines. (231, 232.)

Mr. Greeley estimates that the warehouseman can transfer grain from the car into his elevator and into another car at an expense not to exceed \$2 for a car of 1,500 bushels, while the public pays three-fourths of a cent a bushel, or \$12, to their competitors in the grain business for this service. The elevator man holds the grain and makes the storage charge year in and year out, "and lets these bear speculators hammer the values, and thus assist him to freeze the buyers out and continue the grain in storage." (234.)

Mr. HILL, in his statement before the Illinois legislature in 1897, said the charge of three-fourths of a cent a bushel for transferring grain from cars to vessels, a distance of perhaps 100 feet, was greater than the average freight rate by water during

1895 from Chicago to Buffalo, and that the same grain was transferred on the track from Western to Eastern cars for nothing. (314.)

19. Country buyers.—Mr. RICHARDS says the original shippers of grain in the country have been supplanted by the representatives of the elevators, and selling by sample discontinued. The Chicago elevator men at first tried to do business with the local grain dealers, but it was not satisfactory to the latter, and the elevator men would then put in a dealer, who would begin by paying the farmers a little more than the local dealer, until the old citizen had to go. Then the new dealer ran things to suit himself. No one knows how far he went in the other direction, because there was no one there to watch him; but the farmers felt that they were not getting what they were entitled to. (205, 211.)

Mr. Richards says when a country buyer buys any wheat he reports to his principal in Chicago, who may, if he wishes, sell against it to protect himself from loss. (217.)

Mr. S. H. GREELY believes that the small elevators throughout the West and Northwest are becoming branches of the great central elevators. Chicago men are gradually securing possession of private warehouses in the country, where they purpose buying direct from the farmer. He predicts that this will eventually lead to the larger owning of line houses on the different railroad systems, where one price will be made to the farmers. (233.)

In Mr. HILL'S opinion the present system of handling grain in Chicago, which consolidates the business on a given railroad in the hands of one buyer, is a great detriment not only to the market, but also to the country through which the road runs. Formerly there would be two or more buyers in a town, permanent residents with families, who would buy their goods at home to a certain extent and make business for the town. Now the tendency is to have one grain buyer, a cheap man on \$40 or \$60 a month, who will do the business formerly done by permanent business men of the town. The system destroys competition, and one man dictates the price of grain. (318.)

Mr. Hill testifies that the people who went into the grain business as a result of the change of policy of the railroads were not experienced grain men. For instance, Charles Counselman went into the grain business and tried to run 200 or 300 stations. He was glad to sell out a good many of them, and then began gradually to establish them again. A concern which apparently represents Armour & Co. is gradually taking up elevators, buying out the grain dealers, and going into business under the name of the Neola Elevator Company. (319.)

Mr. WILSON says the present system of selling grain is not very satisfactory to the farmers of Illinois. He thinks there are combinations to control the prices of farm products. The two grain elevators in Magnolia pay absolutely the same price as if there were but one grain dealer in the town. There is no open market. They do not want to work against one another, and they sometimes confer. They get an agreed price by card or telegram. Mr. Wilson thinks these two elevators are not company warehouses. The local grain dealers sell largely on the track, though at times they ship to a terminal point. The country market is governed entirely by the Chicago market, where the grain is sold. (251-253.)

Mr. Wilson says that when a company is formed to own the warehouses along a certain line of railroad the name is not generally made public. The farmers know only the man who is running the elevator. Mr. Wilson has been told that the Illinois Central Railroad is trying to buy the elevators along its line. (252.)

Mr. Wilson testifies that the new line of road being extended through the central part of Illinois (1899) refuses to allow any privileges for individual elevators, and is evidently working with the elevator men. (253.)

C. The Western Elevating Association of Buffalo.—1. **Organization and workings.**—Mr. Cook, secretary of the Western Elevating Association, says that association is an association of 21 or 22 elevators formed for the purpose of centralizing the elevator business, preventing the cutting of elevator charges, maintaining a uniform rate, and giving value to warehouse receipts. The banks will take the receipts of the association without question. The association is formed from year to year. It is simply an agreement between the different elevator owners; there is no stock. The association provides for the collection and distribution of the earnings on the basis of shares or percentage. It did about 95 per cent of the elevator business of Buffalo during the year from April, 1900, to April, 1901. Its charges are one-half cent a bushel for elevating grain and storing it for 10 days; for storage after the first 10 days a quarter of a cent for each 10 days or any part thereof. There is no charge for loading in addition to the elevation rate on through-rail grain, but on local grain there is a charge of one-eighth of a cent for loading. The extra storage during the winter does not run a quarter of a cent for every 10 days all winter long, but

only until the accumulation after the 1st of December amounts to 2 cents. There are no complaints against the charges made.

The independent elevator operators have simply to go into the market and take business on their own hook. The Kellogg elevator is the only one outside the association which is operating at present. It is the only elevator outside the association which has any track connection. Some of the elevators in the association are owned or controlled in some way by railroads, and they have an agreement to handle railroad grain at half a cent a bushel. Their connection with the railroads might have the effect of giving them a better rating in the association. There is no stipulation preventing the railroads from giving a monopoly of the grain business on their respective roads to any particular elevator, though the division of receipts may have the effect of preventing it.

Mr. Cook says the Elevating Association is a great advantage to the trade because it establishes a uniform rate. Each man knows that he is getting as good a rate as his neighbor. (1017-1019.)

2. Effect on independent elevators.—Mr. KELLOGG, proprietor of the Kellogg elevator of Buffalo, N. Y., says the Western Elevating Association has made an agreement with the trunk lines running east to New York to elevate their grain, and the railroads in turn have agreed to pay the association half a cent a bushel on all grain that passes through Buffalo and is shipped by rail. If any grain man wants a rate through the Kellogg elevator, the railroads charge him a half cent higher rate for freight, claiming that, inasmuch as they have made this contract to pay a half cent to the Western Elevating Association, they would be paying double elevation if they paid the Kellogg a half cent. This agreement has been in effect since the 1st of June, 1900, and as a result of it the Kellogg elevator elevates practically no grain at all. The only grain it has any chance of getting is canal grain, and Mr. Kellogg finds reason to believe that since June, 1900, the Western Elevating Association has elevated canal grain free; hence the Kellogg elevator can get neither rail grain nor canal grain. The competition of the Erie canal is not effective in the grain business. Only about 15,000,000 bushels out of a total of 150,000,000 bushels were carried by it in 1900.

Elevator rates are lower now than they were 3 or 4 years ago, but are not so low, Mr. Kellogg thinks, as they would be under competition. The higher rates, while very slight in themselves, aggregate a large amount.

There has been a pool among the elevators for a good many years, but there has been no boycott upon the outsiders until the past year, because the elevator association never before succeeded in getting the railroads to pool with it. (1015, 1016.)

3. Effect on canal forwarders.—Mr. KNAPP, of the firm of Jacus & Co., canal forwarders of Buffalo, N. Y., says that the elevator pool is of benefit to his business, because, on all the grain that comes through the elevator pool, his firm gets free elevation, while the charge to the railroads is half a cent. It is necessary, in order to do any business, to bid half a cent under the railroad in rates, and if his firm had to pay half a cent elevation, it could not compete with the railroads.

The rates to New York by canal are the same on export grain as on grain for home consumption.

There are no elevator companies which do business over the canals only. The all-canal elevators have been driven out of business because the railroads own the majority of the elevators. All of the elevators doing business do both a rail and canal business. About half the storage capacity of Buffalo is controlled by the railroads. (1016, 1017.)

XV. FOREIGN MARKETS FOR AGRICULTURAL PRODUCTS.

A. Present condition of the foreign trade.—**1. Statistics of exports.**—Mr. WEDDERBURN testifies that in 1893 the exports from the United States amounted to \$831,030,785, of which agricultural products amounted to \$615,382,986, or about 74 per cent. Of late years more merchandise has been exported, and the prices of agricultural products have not kept up so well, except during the war; but agricultural products still amount to more than 60 per cent of the total exports. Cotton exports alone are about 40 or 50 per cent of the total. (829.)

Mr. POWERS testifies that the primary and secondary products of agriculture, including meat products, flour, etc., make up 80 or 90 per cent of all exports from this country. (175.)

Mr. HIRCHCOCK, chief of the Section of Foreign Markets in the Department of Agriculture, estimates that about 25 per cent of the total production of American agriculture is exported. With this enormous surplus, the acquisition and maintenance of a

COCXL THE INDUSTRIAL COMMISSION:—AGRICULTURE.

ready foreign market is of the greatest importance, to prevent the glutting of the home market.

"During the last 40 or 50 years our agricultural exports have increased with great rapidity. In 1860 their value was about \$258,000,000; in 1870 it amounted to \$363,000,000; in 1880 to \$693,000,000; in 1890 to \$635,000,000; and in 1899 to \$793,000,000. Comparing 1860 with 1899, the last year for which we have figures, a period of about 40 years, we find an increase of over 200 per cent.

"Every indication points to the probability of a still further increase in our agricultural export trade, provided proper measures are taken to foster it. Modern transportation facilities are revolutionizing the character of the trade. The introduction of cold storage and of refrigeration service on railway cars and steamships is making it possible to market in foreign countries across the sea products that we were formerly unable to export; and it is along this line of development that the increase of our export trade in agricultural products in the future may be chiefly expected—in the exportation of perishable products, such as meats, butter and cheese, perishable vegetables, and fruits.

"Thus far the chief example of trade development along this line is found in the case of fresh beef. In 1880 our exports of fresh beef were valued at about \$7,000,000. Last year (1899) they were valued at \$24,000,000."

The following articles are mentioned as having contributed most to the general increase of the agricultural export trade between 1870 and 1899:

Indian corn: The development of the dairy industry in foreign countries and the discovery that American corn is a cheap and desirable food for live stock have led to an increase in the amount exported from a little over \$1,000,000 to nearly \$70,000,000.

Wheat flour, from \$20,000,000 to \$73,000,000; the remarkable development of the milling industry in this country, resulting in a large production of high-grade flour at low cost, has made it possible to export flour in competition with other countries, and gradually get the trade.

Cattle, from less than \$500,000 to over \$30,000,000, this trade being greatly aided by improvement of transportation facilities, and by the official inspection of export cattle.

Bacon and hams, from \$6,000,000 to over \$60,000,000.

Lard, from \$6,000,000 to \$42,000,000.

Oil cake and oil-cake meal, which are beginning to be fed very largely to live stock in dairying countries, from \$3,500,000 to \$14,500,000.

Cotton-seed oil, from \$15,000 to \$12,000,000, the increase being especially marked in 1898 and 1899; the exports increasing from 27,000,000 gallons in 1897 to 51,000,000 gallons in 1899.

Oleo oil, sent abroad in the crude form to countries which manufacture oleomargarine, from nothing to over \$9,000,000.

Fruits, from \$500,000 to nearly \$8,000,000. (666, 667, 671.)

Oleo oil and butter.—Mr. HITCHCOCK adds that our exports of oleo oil for the 5 years 1894–1898 averaged about 110,000,000 pounds, valued at \$8,357,000, while the average exportation of butter was only 18,764,000 pounds, and the value about \$2,858,000. The oleo oil is used chiefly for manufacturing imitation butter in the Netherlands and in other countries. The manufacture of oleomargarine is carried on most extensively in the Netherlands, the exports from that country exceeding 100,000,000 pounds a year, of which by far the largest part goes to the United Kingdom, while the remainder is distributed quite generally over Europe and to some extent through tropical countries. While artificial butter is now used quite extensively in Europe, the consumption of real butter has also increased; the poorer classes are beginning to use it much more than formerly. In the United Kingdom, the most important butter market of the world, imports of butter from all sources amounted in 1886 to about 173,000,000 pounds; in 1899, to about 380,000,000 pounds. The increasing exports from the principal export countries which show a rapid development are chiefly due to this growing demand of the British market. (672, 678.)

Horse meat.—Dr. SALMON says Congress provided two or three years ago that horses should be entitled to the same inspection as other animals. On account of the low price of horses in the range country, it was believed that horses could be slaughtered to advantage for export; but Dr. Salmon does not believe that it has been very successful. The first year about 3,200 were slaughtered, and in 1899–1900 5,559. Federal inspection has been established at only one place, which is in Oregon; but horses have been slaughtered at other points without Federal inspection, e. g. in Chicago and in Brooklyn. The horse meat goes partly to Norway and partly to Holland, but it is hard to say where it is consumed. There have been rumors that it has been made up into bolognas and sent back to America. (750.)

Fruit.—Mr. NARTZGER testifies that only a small quantity of the green and citrus fruits of California goes abroad, though the shipments of oranges to Liverpool and London are being increased. A good deal of canned and dried fruit is exported. (965.)

2. Distribution of exports.—Mr. HITCHCOCK testifies that more than half of all our agricultural exports are sent to the United Kingdom. During the 5 years 1894–1898 about 55 per cent of the products exported, measured in value, went to the United Kingdom, 13 per cent to Germany, 6.8 per cent to France, 4.3 per cent to the Netherlands, and 3.6 per cent to Belgium, these 5 countries being the destinations of a very large proportion of our agricultural exports. Of our agricultural exports for the 5 years named, about 88 per cent went to European countries. (667.)

Mr. Hitchcock says France is an agricultural nation, producing an abundant food supply, and hence the United States has always found it difficult to market agricul-

tural products there. The difficulty is increased by rather stringent tariff legislation enacted in the interest of French agriculture, and by a certain prejudice against some American products, especially meat. (670.)

Mr. Hitchcock states the quantity and value of each of the principal agricultural exports shipped to each of the most important foreign markets, showing the percentages in each case, as follows:

Indian corn.—United Kingdom, 43 per cent; Germany, 17 per cent; Canada, 9 per cent; Netherlands, nearly 9 per cent; Denmark, nearly 8 per cent; France and Belgium being the next most important markets.

Wheat flour.—United Kingdom, 58 per cent; Netherlands, 6 per cent; Hongkong, 5 per cent; Brazil, Canada, the British West Indies, Cuba, and Germany coming next in order of importance.

Live cattle.—United Kingdom, 96 per cent, being the only market of importance, though we have recently been shipping a number of cattle to Cuba (about 40,000 head in 1898).

Lard.—United Kingdom, 36 per cent; Germany, 27 per cent; Netherlands, 8 per cent; Belgium, 6 per cent; France, 5 per cent.

Live hogs are not exported to any considerable extent, the annual exports averaging only about 14,500 during the 5 years, of which Mexico received 67 per cent, Canada 15 per cent, and the Hawaiian Islands 13 per cent.

Fresh pork went chiefly to the United Kingdom, shipments to other countries being inconsiderable.

Salted or pickled pork.—United Kingdom, 22 per cent, the remainder going chiefly to Haiti, Canada, the British West Indies, Porto Rico, British Guiana, and Germany, Germany's share being less than 5 per cent of the total.

Bacon.—United Kingdom, 77 per cent; Belgium, 6 per cent; Germany, 5 per cent; Brazil, 3 per cent; Netherlands, 2 per cent.

Hams.—United Kingdom, 81 per cent; Belgium, 6 per cent; Cuba, 3 per cent; Germany, 3 per cent; Canada, 2 per cent; Netherlands, slightly more than 1 per cent.

Cotton-seed oil cake and oil-cake meal.—Germany, 47 per cent; United Kingdom, 27 per cent; Denmark, 11 per cent; Netherlands, 9 per cent; Belgium, 3 per cent; France, 2 per cent.

Flaxseed oil cake and oil-cake meal.—United Kingdom, 48 per cent; Belgium, 26 per cent; Netherlands, 14 per cent; France, 5 per cent; Germany, 3 per cent; British West Indies, 3 per cent.

Cotton-seed oil.—France, 27 per cent; Netherlands, 23 per cent; United Kingdom, 9 per cent; Germany, 8 per cent; Austria-Hungary, 8 per cent; Mexico, 6 per cent; Italy, 5 per cent.

Oleo oil.—Netherlands, 60 per cent; Germany, 23 per cent; United Kingdom, 7 per cent; Sweden and Norway, 4 per cent; Denmark, 3 per cent; Belgium, slightly more than 1 per cent. (668-672.)

3. Recent development of the Pacific trade.—Mr. HANLEY says it is only recently that the United States began to trade with Japan and China. The first shipments of flour were taken at \$2.50 a ton, but as the demand for shipping facilities increased the rate was raised to \$3 and \$4 and as high as \$6 a ton. He understands that even at these high rates half the flour offered for shipment has to be refused for lack of vessels; also that 100,000 bales of cotton and 50,000 tons of steel rails were refused for the same reason, and that all the available shipping capacity up to the middle of August, 1899, was contracted for in the early spring. (294.)

Mr. NARTZGER testifies that the total Pacific exports of all classes of merchandise to Asiatic countries for the fiscal year ending June 30, 1898, was nearly \$17,000,000, a gain of over 400 per cent in 5 years. The exports of fruits, including canned fruits, from Pacific coast ports to foreign countries for that year amounted to \$1,721,000. (949.)

Mr. HITCHCOCK testifies that the total value of our agricultural exports to Asia increased from less than \$4,000,000 in 1894 to nearly \$15,000,000 in 1898, while those to Oceania increased from less than \$2,000,000 to \$3,500,000, the increase to Asia and Oceania being proportionately very much greater than in any other direction. The chief agricultural exports from the Pacific coast are cotton and wheat flour.

The total exports of raw cotton to Japan, China, and Hongkong increased from 23,500 pounds in 1889 to about 32,000,000 pounds in 1897, and nearly 119,000,000 in 1898. The raw cotton goes chiefly to Japan, where the manufacture of cotton is rapidly coming into prominence. Our exports of cotton manufactures to the Orient also show a considerable increase—from \$1,600,000 worth to \$5,300,000 worth during the same decade. The natural inference is that the use of cotton cloths is increasing in that part of the world. Mr. Hitchcock understands that the South is beginning to export cotton goods quite largely to the Orient.

The exports of wheat flour to Japan, China, and Hongkong increased from 408,000 barrels in 1889 to 676,000 barrels in 1894, and to 1,120,000 barrels in 1898. (667, 668.)

Mr. TURNBULL presents tables showing the imports of foreign merchandise and the exports of domestic merchandise at the Pacific ports for the fiscal years 1888-1898. The imports have remained nearly stationary during that time, though with considerable variations from year to year. The exports have also varied greatly from year to year, but have, on the whole, considerably increased. For the whole period the imports exceeded the exports by less than 2½ per cent. A detailed table of trade between the Pacific ports and the various countries of Oceania and Asia is also given. The trade with Japan is on the whole the most important in amount, and that with the Hawaiian Islands comes next, with China in third place. The imports considerably exceed the exports, though the difference has greatly decreased. A table showing the relative importance of the foreign trade of the several Pacific ports is also

given. In the fiscal year 1898 San Francisco received imports of \$43,000,000 out of the total Pacific coast imports of \$52,000,000. Of the aggregate exports of nearly \$75,000,000, nearly \$41,000,000 went through San Francisco, nearly \$18,000,000 from Puget Sound, and nearly \$14,000,000 from Willamette, Oreg. The exports from Puget Sound are stated to consist largely of lumber. Other tables show the apportionment of the commerce of the Pacific coast among the grand divisions of the world, and give the values of different classes of articles imported and exported through the Pacific ports. (982, 989-993.)

California grain.—Mr. TURNBULL states that California grain is shipped to Europe, to China, and to the East generally. He thinks that about three-fourths of it goes around the Horn to the Atlantic coast or to Europe. (983, 985.)

California fruits.—Mr. NAFTZGER testifies that the Southern California Fruit Exchange markets a quantity of citrus fruit in Europe, as well as at all points in the United States. There are some efforts to make a market in Asia, but the California fruits do not stand the long voyage as well as the Mediterranean fruits. Vast quantities of canned fruits go to Asiatic countries. The South Sea countries can not be reached because the freight rate is higher than from England. Canned fruit constitutes about 10 per cent of the shipments of fruit out of California. A considerable quantity of California canned fruit, especially citrus fruit, is shipped to Alaska, and there is quite a large business in canned and dried fruit with Alaska. (949.)

4. *South American trade.*—While in South America Professor DAVENPORT found that nearly all the trade of that country was with Europe, apparently for two reasons: (1) European nations had the shipping facilities, and (2) they had made a study of the export trade, and had learned that the tastes and prejudices of the buyers must be consulted as well as their real needs. The South American countries import certain food products extensively from Europe; for example, butter. They import hams from America and codfish from Newfoundland. Though the Amazon River is the richest river for fish in the world, Professor Davenport saw in cities along the Amazon 10 times as many codfish as he ever saw in this country. (269, 270.)

B. Complaints against American products.—Mr. SNOW testifies that there is in a number of European countries a prejudice against American food products, which he believes to be due to the fact that Americans have not been careful to export the best goods, the export trade having been considered largely as a means of working off the surplus not desired at home. Some of the other export countries, such as Denmark, Australia, and New Zealand, have followed the opposite course, and exported the very best grades of their dairy products. (239.)

1. *Grain.*—Mr. HITCHCOCK says that within the last few years many complaints have been made with regard to the condition in which some American grain arrives at foreign ports. It has been claimed that much moldy grain has been received at European ports, and also to some extent that grain of a grade inferior to that of the certificate upon which it was purchased has been received. (679.)

Mr. Hitchcock thinks he is safe in saying that the greatest obstacle to the maintenance and extension of the American grain export trade lies in the fact that the exporters do not always exercise proper care in cleaning the grain before shipment. In view of the increasing competition of other countries it is highly important that this ground for complaint should be remedied. There has been quite a general complaint that American corn is too dirty, and does not compare favorably in this regard with that shipped from other countries. The corn frequently contains broken grains and pieces of cob, which fill in the interstices between the grains and increase the danger of sweating, and sometimes foreign substances, including even metallic articles which damage the milling machinery. If the corn were cleaned more carefully a great deal of loss would be avoided. Corn shellers are sometimes stationed in the open field, and the corn is dumped on the ground in piles and shoveled from the ground into the shellers. Foreign objects of a less size than the cobs readily pass through the shellers, and remain in the corn unless it is screened. The railway cars are not always properly cleaned before the grain is loaded, and the terminal warehouse may also be at fault. Complaint has been made abroad against American wheat that it sometimes contains many unsound and burnt grains, more than would be warranted by the certificate of inspection, and that it is sometimes deficient in weight. Mr. Hitchcock mentions one case of complaint against wheat which contained so much garlic that it was necessary to reclean it. One of the complaints against rye from the United States is that it too frequently contains oats, making it necessary to reclean it before it can be made into flour. American barley has also been complained of because of its dirty condition. Some years ago American barley was held in high favor abroad, and it obtained a market in Europe that was formerly controlled by Russia; but within the last few years complaints against its condition have become numerous, greatly endangering the market. Unless measures are taken

to secure more care in cleaning export barley much trade will probably be lost. (682, 683.)

Mr. Hitchcock believes, however, that most of the damage to grain occurs on the voyage. Corn gets out of condition more readily than the other grains, because its content of moisture is greater, and most of the complaints have been made about corn. Sometimes when corn in otherwise perfect condition is loaded here in hot weather, the heat causes it to sweat and become moldy before it reaches the other side. Much of the damage occurs in the case of bulk cargoes carried by tramp steamers, the regular liners giving greater attention to ventilation and to care of the cargo generally. (1) Ventilation is a very important factor. When corn is loaded into a steamer at a southern port in hot weather and carried across the ocean without ventilation, the chances are very strong that sweating will occur. The corn is apt to become heated at the top from the heat of the sun on the deck. The tramp steamers frequently do not have a sufficient force of men to attend to the ventilation properly. Mr. Hitchcock understands that steamers carrying corn from Argentina to Europe are now very generally equipped with ventilation facilities. (2) Corn is sometimes loaded into iron steamers without any protection against the iron sides, which are heated by the sun. There should be either a board sheathing or a protection of bagging. (3) Corn is sometimes loaded into the coal bunkers or holds adjacent to the boiler or engine space, and becomes heated from the furnaces and boilers. (4) Grain is sometimes stowed with other merchandise in the same hold. A case has come to Mr. Hitchcock's attention in which corn was covered with bales of cotton, resulting in sweating. (681, 682, 684.)

Inspection of export grain.—Mr. HITCHCOCK says that as a rule our grain is sold on the certificates of inspection furnished by the boards of trade and chambers of commerce at the ports of shipment, and under the rules of these bodies the certificate is conclusive, the importer having no redress if he considers that the grain does not correspond to the grade certified to. Mr. Hitchcock thinks there may be some carelessness in the inspection of export grain, but is inclined to think that the complaints based upon the ground of fraud are mostly unfounded. Unfortunately the methods of inspection lack uniformity. Each board of trade or chamber of commerce adopts its own rules of inspection and regulations for grading. In most cases the grades are changed somewhat from year to year, following the average condition of the crop, but changes in the crops are not followed as carefully in some ports as in others, and in some the grades remain practically the same from year to year. The representatives in this country of foreign importers of grain are supposed to notify their firms of any changes in grading, but it often happens that this is not properly done. A great deal of grain is now shipped from Southern ports, where the rules of grading sometimes differ slightly from those in force in New York and Chicago. The importer who has received one certified grade and then receives an inferior quality under the same certificate, not understanding the conditions, would naturally feel that the second consignment fell short of the standard called for. The changes in grading are most noticeable in corn, and it has been chiefly against corn that these complaints have been made. The certificates issued by the commercial bodies usually bear the inscription "Official inspection certificate," and foreign importers and buyers quite generally understand that to mean a Government certificate. Mr. Hitchcock suggests that commercial bodies be prohibited from using the misleading word "official" on their certificates. He believes that a uniform system of grading at all ports of shipment would be a great advantage to the export trade. He thinks, however, that considering the wide distances between the various ports and the different conditions that prevail, the present system of inspection is a remarkably good one. (679, 680, 681, 683.)

2. *Cotton.*—Mr. HITCHCOCK says that while cotton is our most important agricultural export, there are many cases where failure to give proper attention to packing is working to the detriment of the export trade, and it is very important that greater care should be taken in that respect. The principal ground of criticism against American cotton in foreign markets is the poor packing. A great deal of cotton is still baled in the old way, in large bales of about 500 pounds, and much of it is put up in inferior baling materials. The packing is generally sufficiently strong to carry the cotton to seaboard, but when it comes to be unloaded, under the rough handling to which it is subjected, the flimsy baling material becomes badly torn, and usually a large amount of cotton is shredded off and strewn along the wharves. Before the cotton can be reshipped much patching and often entire rebaling has to be done, subjecting the importers to much additional expense. Most cotton sent to Russia is transhipped at such ports as Liverpool, Bremen, and Copenhagen (though the United Steamship Company of Copenhagen has recently been carrying cotton direct from New York to St. Petersburg), and by the time it has been discharged at the Russian ports

the baling is apt to be in very poor condition. From the Baltic ports it must be sent overland by rail to Moscow, where the Russian manufacture of cotton goods is chiefly carried on. Owing to the enormous rents in the bale coverings a great deal of the cotton is lost. It generally goes by slow freight, with many stops; and Mr. Hitchcock was informed when in Russia that the peasants along the route sometimes stole great quantities of the cotton from the trains at night, pulling it from the damaged bales in large shreds. In this manner the Moscow importers have lost so much of their consignments from America that they are striving to replace American cotton with that produced in southern Russia, where American cotton is beginning to be grown quite extensively. The Russians have secured American seed and have had considerable success in the production of upland cotton. They use a smaller bale than the American, packing the cotton so tightly that none can be lost or stolen, and by these methods are establishing quite a trade at Moscow. (684, 685.)

Mr. Hitchcock characterizes the use of the cheapest possible baling materials in order to save a few cents on a bale a shortsighted practice which is certain to do great damage to the trade. He expresses the hope that the more general adoption of the round or cylindrical bale will remedy the difficulty. (685.)

3. Exclusion of American cattle from European countries.—Dr. SALMON says that in 1899 American cattle were prohibited from going inland in Great Britain for sale, and were confined to a few "foreign-animal wharves," to be killed within 10 days, on account of the existence of contagious pleuro-pneumonia in this country at that time. This is thought to have reduced the value of every American steer exported at least \$5; an enormous loss in the aggregate. In 1881, or soon after, nearly every country on the continent of Europe excluded American pork for the alleged reason that it contained trichinae. This regulation was kept in force 10 years, ruining a growing trade which we have been only partially able to regain. Still later, American sheep have been required to be sold at the foreign-animal wharves of Great Britain on account of the scab. Our live cattle and fresh beef have been excluded from Germany, Denmark, and Belgium, and our cattle from France, because of Texas fever. Our entire live-animal trade with Great Britain was menaced because of the sufferings of animals in transit, which shocked the people of that country; but the legislation antagonistic to this trade appears to have been abandoned because of the establishment of regulations for the humane treatment of animals during the voyage. Our live swine are excluded from most European countries on account of cholera, and our canned beef has been excluded from Germany. (747, 748.)

Dr. Salmon says we should not have an export trade in live stock had it not been for our inspection regulations; because after the first step in confining American animals to foreign-animal wharves on the other side the agitation was very strong for the entire prohibition of trade in live animals. There was a bill in Parliament, which appeared likely to pass, prohibiting the carrying of live animals, on the grounds of cruelty to animals in transit and their arrival in bad shape for slaughter; but when the regulations were made specifying how the ships should be fitted up, the legislation was dropped. (751.)

Mr. HITCHCOCK says the importation of American live cattle into Germany, France, Belgium, and the Netherlands was prohibited some years ago, though Belgium has since removed the prohibition. The prohibition was enacted on the supposition that there was danger of introducing infectious diseases. There were some alleged cases of Texas fever in American cattle shipped to Hamburg, on the strength of which Germany prohibited the importation of live cattle from the United States, and the other countries named afterwards took similar action. It is generally believed that the Agrarian party in Germany is back of this movement, and that the chief object is really to protect German products against competition. Mr. Hitchcock believes that under the inspection system of the Department of Agriculture there is little danger of sending diseased cattle out of this country. (669, 670.)

4. Dairy products.—Mr. SNOW testifies that at one time this country enjoyed a very large export trade in dairy products, especially cheese, which has been almost entirely destroyed by the shipment of filled cheese, in which the natural fats were replaced by cheap greases. (236.)

Mr. HITCHCOCK calls attention to a striking decline in the export of butter and cheese. The exports of butter have fallen from 39,237,000 pounds in 1880, which represented about the height of the export trade in butter, to 5,599,000 pounds in 1895. During the last few years the trade has been improving a little, about 20,248,000 pounds being exported in 1899, only about one-half, however, of what was exported 20 years ago. Mr. Hitchcock says the increase in the production and consumption of imitation butter has never affected the consumption of butter, but that most butter companies have increased their exports of butter. The chief cause of the decline in the American exports he finds in the unfortunate management of

the export trade, and the inferior grades of butter American exporters sent to foreign markets, especially to the United Kingdom, the chief butter market. After a trade of considerable importance and a fair reputation for our butter had been established, unscrupulous exporters took advantage of the situation to dispose of inferior butter. The lack of any Government inspection of export butter enabled them to export process butter, labeled as they pleased. Large quantities were sent to the English market and brought American butter as a whole into disrepute. Even in the first place we did not, as a rule, send our best butters abroad, but exported in large quantities inferior grades that could not be sold readily at home. (672.)

Our experience in the exportation of cheese has been practically the same as with butter. The exports reached the highest point in 1881, 147,996,000 pounds, with a value of \$16,380,000. In 1899 they amounted to only 38,199,000 pounds, valued at \$3,316,000, a loss of over 100,000,000 pounds in 20 years. The reason for this, Mr. Hitchcock says, was essentially the same as the reason for the decline in the exportation of butter, namely, the shipment of an inferior product, especially the shipment of large quantities of filled cheese. (676.)

C. Foreign competition.—Mr. Hitchcock says that when an inferior quality of one of our products causes it to find a less ready sale in the foreign market, our competitors are quick to take advantage of the opening thus offered. It is only of late that this foreign competition has been assuming such great importance. It has become a more vital question within the last few years because of the measures taken by competing countries to control the foreign markets upon which we have hitherto depended. Foreign countries have done more within the last decade than ever before in the way of pushing agricultural exports by governmental assistance. Mr. Hitchcock therefore considers it important for the United States to take more active measures in regard to exports. (689.)

1. Danish butter and bacon.—Mr. Hitchcock says the Danes have been preeminently successful in meeting the requirements of foreign markets, and especially of the British market. In 1880 Denmark exported about 27,498,000 pounds of butter, having a value of about \$4,305,000. In 1898 the exports had increased to 160,143,000 pounds, worth \$34,576,000. This butter is sent almost exclusively to the British market, and is made with special reference to its requirements. It has been the policy of the Danish Government first to establish a reputation for its products in foreign markets, and then to compel producers to maintain the high standard. The butter export trade is practically under Government supervision. Butter for export is carefully inspected under direction of the Royal Agricultural Society, acting for the Government, and no butter is allowed to go out of the country that does not come up to the required standard. Danish export butter is all of one grade. The English importers simply order so much Danish butter, and pay for it at the market quotation; they practically have a Government guaranty that the butter will come up to a certain standard. There is a difference of 3 or 4 cents a pound between high-grade Danish butter and the ordinary American or Canadian butter. The average import price in the United Kingdom of Danish butter in 1899 was 22.95 cents a pound. During the same year the butter imported from the United States averaged 19.2 cents a pound and that from Canada 19.4 cents a pound. Danish butter always brings the highest price of any butter imported into the United Kingdom, except the fresh unsalted butter from Normandy, which is within 24 hours from the churn.

The Danes are regarded to a certain extent as the pioneers in butter production by modern methods; they have been the models both in production and in export methods for the various countries which are rapidly developing an export trade in butter. Mr. Hitchcock understands that the Danish butter is made almost altogether of pasteurized cream, and its remarkable uniformity is attributed to that fact. Several years ago, under Secretary Rusk's administration, the Department of Agriculture sent a special agent to Denmark to investigate the dairy industry, and he made a very thorough and comprehensive report. The Department considers it possible for the United States to send to the British market a butter equal in quality to the Danish.

Soon after they had placed their export trade in butter on a sure footing the Danes began to reach out after the market for bacon in Great Britain. They studied the wants of the British market and produced a bacon that met those wants. In 1880 they exported about 13,000,000 pounds of pork, chiefly bacon. In 1898 they exported 135,000,000 pounds, sending most of it to Great Britain. Canada took the same measures that Denmark had taken to get at the requirements of Great Britain. In 1890 Canada shipped about 7,000,000 pounds of bacon, chiefly to Great Britain. In 1899 the Canadian exports amounted to nearly 112,000,000 pounds. Our own exports of bacon, though enormous, do not show any such growth, and there seems to be danger of a decline; they amounted in 1881 to 673,000,000 pounds; in 1890 to 532,000,000 pounds;

in 1895 to 453,000,000 pounds, and in 1899 to 563,000,000 pounds, more than in 1890 or 1895 but considerably less than in 1881, which was about the time the bacon shipments from Denmark and Canada were beginning to become prominent. Mr. Hitchcock suggests that we may feel still more seriously the competition of those countries and of the Australasian colonies unless measures are taken to adapt the American product more closely to the requirements of the British market. The bacon preferred in that market is the Wiltshire bacon, which is much leaner and firmer than ours. Our bacon is considered too fat, being corn-fed, and it does not bring as high a price. In 1899 the average price of bacon imported into the United Kingdom from the United States was 6.96 cents a pound; from Canada, 7.3 cents a pound; and from Denmark, 10.6 cents a pound. As most of the 563,000,000 pounds of bacon exported from the United States went to Great Britain, even a slight enhancement in price would have meant an enormous gain to the American farmer. The Tamworth and Yorkshire swine seem to be the preferred breeds for producing bacon for the British market. (673, 675, 676, 687.)

2. Butter from other European countries.—Mr. HITCHCOCK testifies that the Swedes and Finns have developed an important export trade in butter in the last decade. They produce a butter practically the same as Danish butter, and ship it to the British market in increasing quantities each year. Hitherto a large quantity of this butter has gone to Denmark, and a considerable portion has undoubtedly been re-exported as Danish butter.

"Even Russia is also beginning to develop an export trade in butter. The Baltic provinces, especially, are giving their attention to this industry, and are taking active measures to develop it—measures similar to those taken by Denmark. The Russians are engaging Danish experts to install their creameries and to instruct their butter makers. Already they are beginning to ship a high grade of butter, some of which is sent to the British market, and finds there a ready sale.

"These various countries, none of which has greater dairying possibilities than the United States, are thus developing and widening their export trade in this commodity, while we, because of our unbusinesslike methods, have been losing the little export business that we formerly possessed." (674.)

3. Canadian cheese, butter, etc.—Mr. SNOW testifies that Canada has a very large export trade in cheese, which has continued to grow, while the United States, whose trade in cheese was formerly larger than Canada's, now exports practically none. (237.)

Dr. SALMON testifies that our export trade in butter and cheese with England has been greatly injured by the shipment of adulterated and renovated butter and filled cheese as first-class products. Canada, by supervising the manufacture and indorsing the goods, has won the market away from our own exporters, and some of our best dairy products now find their way to Great Britain by way of Canada, branded as Canadian goods. (748.)

Mr. HITCHCOCK also testifies that our export trade in cheese has been lost to Canada. The Canadian government not only prevents the manufacture of filled cheese, but took measures to improve the quality of the Canadian product and to secure a ready sale in the British market. Canada saw an opportunity to establish a trade when that of the United States began to fall off, and made the most of it. The exports from Canada increased from 40,369,000 pounds in 1880 to 94,260,000 pounds in 1890, and reached the enormous total of 189,828,000 pounds in 1899, an increase due very largely to the measures taken by the Canadian government. The government began by helping manufacturers. It gives liberal bonuses for building factories, and under the supervision of the Ministry of Agriculture established a system of instruction and inspection that resulted in a rapid improvement in the methods of cheese production. As the surplus increased the government secured for exporters favorable transportation facilities. (676.)

The Danes have developed the butter export business much more extensively than Canada, although of late the Canadians have taken steps to push the export of butter as they have the exports of cheese, and a policy similar to that of Denmark has been adopted. The Canadian trade fell off at about the same time as that of the United States. In 1880 Canada exported 18,535,000 pounds of butter. In 1890 very little export business was done, less than 2,000,000 pounds going abroad. In 1899, under the measures taken to reestablish the business, the amount came up to about 20,000,000 pounds, or about as much as in 1880. (673, 674.)

The Canadian government has assisted in the manufacture of cheese and butter by giving liberal bonuses to factories and creameries and establishing a system of cold-storage transportation. The government offered a bonus of \$100 to creameries that would install and maintain cold-storage facilities, \$50 to be paid the first year, \$25 the second, and \$25 the third. The government also secured cold-storage facilities upon railroads, so that after being cooled at the creamery the butter would go directly into a refrigerator car, and established a cold-storage warehouse at the ter-

minal of the railroad so that the butter could be kept safely before loading upon the ship. The government also secured refrigeration service on steamship lines to the British ports.

"This cold-storage system was installed according to instructions prepared by the department of agriculture, and, in some cases at least, Parliament defrayed the expense of installation. To give the trade a start, the government contracted with the steamship companies for cold-storage space, put in the necessary refrigerator chambers, and then guaranteed to the steamship company the full freight charges for the service. Under these conditions very favorable transportation rates were procured, and as the initial expense was borne partly by the government, it was possible for the Canadian producers to send their dairy products to the British market at very low rates. In this manner a great inducement to exportation was offered.

"The government also watched very carefully the quality of the product shipped, issued instructions as to methods of packing, branding, labeling, etc., and in fact practically supervised the entire exportation. Numerous trial shipments were also made by the government, the government purchasing the produce and sending it over and disposing of it through its own agents abroad."

These trial shipments were not confined to dairy products. Fruits, for instance, were exported in the same way. (676, 677.)

4. Development of the Australasian export trade.—Mr. HITCHCOCK says the measures adopted in Australasia for the development of the export trade correspond rather closely to what has been done in Denmark and Canada, but if anything the Australasian colonies have gone even further than the other countries. In 1895 the government of New South Wales appointed a Board for Exports to consider plans for the development of a larger export trade. The leading producers and shippers of the various export commodities were called into consultation by the board and their opinions asked as to the best measures to be taken to assist their particular branches of trade. As a result of these conferences a great deal of valuable information was elicited, and on the strength of what it thus learned the board made recommendations to the government which were carried out.

One of the first things done by the Australasian colonies to facilitate their export trade was the securing of better transportation facilities by rail to the ports of shipment. Cold storage on trains was procured as it had been in Canada. Cold-storage warehouses were established at the ports of shipment, and arrangements were made with the steamship companies to provide regular sailings to the British market and to furnish refrigeration facilities on board. Several of the colonies also established cold-storage depots and warehouses at London and other British ports under the management of agents who received the produce, kept it in cold storage when necessary, and took measures for its proper disposal in the market. The establishment of these terminal depots has rendered great assistance to the Australasian export trade. The colonies have also adopted the policy of sending agents to study the methods of other export countries. Their agents have come to the United States and Canada and have visited Denmark and other countries, reporting to their own governments the results of their investigations. (688.)

The Australasian colonies have also adopted one of the most important plans inaugurated by Denmark, namely, that of offering prizes for products put up in the best shape for export. The government furnishes the producers with careful instructions as to the kind of product, style of packing, labeling, etc., desired by the export trade, and contests are held, at which liberal prizes are offered for the products best filling the requirements. This plan has been an important factor in the Australasian colonies, as it was in Denmark. (688, 689.)

The butter exports from the Australasian colonies to the United Kingdom increased from less than 4,000,000 pounds in 1889 to over 40,000,000 pounds in 1899. (674.)

D. Possible extension of foreign trade.—1. **Need of public and private effort.**—Mr. BRIGHAM, Assistant Secretary of Agriculture, and Mr. JONES, master of the National Grange, both emphasize the desirability of extending foreign markets for American agricultural products. Our consuls should be familiar with the conditions of agriculture and the needs of foreign countries for our farm products. At present the Government does much more to push American manufactured products in foreign countries than it does agricultural products.

Mr. Brigham urges that foreign buyers should be protected against frauds in American goods, especially in butter and cheese, which would also prove to the advantage of the American farmer. Mr. Jones adds that farmers have no desire to curtail the exportation of manufactured products or the assistance given to them by our consular service. The farmer profits by the prosperity of the manufacturer. Nevertheless his profit is not so direct as that of the manufacturer, and he should receive attention on his own behalf. Increased prosperity of the farmer would increase his demand for manufactured goods. (Brigham 22, Jones 31, 32.)

Mr. NORRIS, master of the New York State Grange, says the United States, being a country that produces more than it consumes, should plan to market its products

CCCLXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

in the Old World. The export of grain to China will be a great benefit to this country in time. Canada and the United States are the fruit-producing countries of the world, and foreign countries are depending upon our fruit more than ever before. Our trade is being sought in Germany, France, and England, and our exports are increasing from year to year. The problem to be solved is to give them honest products of as good quality as they can produce for less money than they can produce them for. (331.)

Mr. DYE says that the Department of Agriculture and the consular service could do much to extend foreign markets for agricultural products by showing foreigners the value of American cereals, especially wheat, and teaching them to use these articles. This is especially desirable in Asiatic countries. (96.)

Mr. HANLEY says cotton is even more subject to long-continued depression than the wheat crop, because we consume only about one-third of the cotton crop and must rely on export trade to take the other two-thirds. He calls attention to the necessity of extending and establishing foreign markets and securing new customers for this article. (289.)

Mr. HITCHCOCK says that comparatively little effort has been made in the interests of the farmers of the United States as regards export markets. The manufacturer seems able to accomplish more in that direction; he sends his representatives abroad, establishes agencies, and keeps in closer touch with the foreign market than the farmer does. It is not so easy for the farmer to do this, because the agricultural interests are not concentrated in the hands of a few men.

Mr. Hitchcock believes that the Department of Agriculture should be provided with more liberal means to develop the agricultural export trade. Not nearly as much has been done as in other agricultural countries. The fund placed at the disposal of the Agricultural Department for making experimental shipments of dairy and other produce was only \$25,000, while the corresponding appropriation in the Dominion of Canada was \$100,000, and the Australian colonies also have been liberal in appropriating funds to assist the farmers in finding foreign markets. It is of the highest importance to study the peculiar tastes and requirements of the various foreign countries, and to put up products that will be acceptable in the market to which they are sent. (685, 687.)

Professor DAVENPORT says the way to increase our foreign trade is to learn what certain countries want, make a close study of the consuming habits of the people, learn in what shape our products can go most successfully to their markets, and meet their habits as nearly as possible. Agriculturists should produce definite things for export and see to it that they are always of one grade. The consumer of imported goods wants them uniform. The dealers will have to help in this matter. Professor Davenport commends Secretary Wilson's test exportations of butter for London markets as the right way of beginning. (270.)

Mr. STOCKWELL says the farmers of Massachusetts are not working for a foreign market; their productions are largely for the home market. A good foreign market raises the price in the home market, however. (895.)

2. Desirability of further developing Oriental markets.—Mr. HANLEY says the only thing that will make farming profitable for every part of the country is the development of Oriental markets. England is now practically our only customer. Any agency that will create a competing market will stimulate prices. Any advance in price would go to the producer, as the freight rates and handling charges are in operation whether prices are high or low. Estimating the increase in the price of wheat at 15 to 20 cents a bushel, Mr. Hanley says the annual gain to the American farmer would be from \$75,000,000 to \$100,000,000 on wheat alone. The wheat belt, being about midway between the Atlantic and Pacific oceans, is so situated as to enjoy the competition that Asiatic trade would establish, and the advantages that could be obtained by transportation lines going both west and east and establishing competitive rates to attract the crop in their respective directions. He believes that wheat could be moved from the wheat belt to the Pacific coast for what it costs to take it to the Atlantic seaboard, as high rates are often maintained in order to provide for the cost of hauling back empty cars. This new route would become the great equalizer of rates, and would build up new industries and commerce. (287, 288.)

Mr. Hanley adds that the population of China, to which we have direct and easy access from the sea, is about 400,000,000. If we could get them to take the 40,000,000 bushels of wheat produced on our western slope, it would be less than half a peck for each inhabitant, or not as much as would furnish pie crust for the wealthy inhabitants of that country. A large percentage of these people are wealthy or in moderate circumstances. It would not be an insurmountable task to cater to the tastes of this large, intelligent, and wealthy middle class and introduce a palatable and nutritious

article of food that would be moderately cheap as compared with rice food. History has shown that wheat flour has displaced rice flour wherever they have come into competition. (289.)

Mr. MORAN also advocates extending our markets into the Oriental countries, where two-thirds of the inhabitants of the globe dwell. (719.)

Dr. CROWELL says that if the price can be put low enough we can sell a very large proportion of the Western wheat to Japan and China. If the Trans-Siberian Railroad can handle wheat more cheaply than our railroads are willing to handle it, it may be possible for the Siberian farmer to put grain in South America or on the Pacific coast at a lower price than that at which it can be bought from American producers. The future conflict for the ascendancy of American agriculture is to be on the Pacific. (343.)

Mr. POWERS predicts that there will ultimately be an immense market in Asia for some American agricultural products, and that a wise policy with reference to the Orient will give American farmers entrance to a market equal to that of Europe. (191.)

3. Increased exportation of corn impracticable and undesirable.—Professor DAVENPORT doubts the practicability of introducing American corn into Europe as a food product. The cheap grain of European nations is rye, and they can not produce corn. Corn is exported to western Europe for food for cattle and pigs, and it is not customary in any country to use for human consumption the same grain that is fed to animals, unless it is raised in that country. Professor Davenport thinks it much better to export corn in the condensed form of meat, and believes that we should at some time retire from the export of grain, though the Mississippi Valley can doubtless stand a heavy exportation of grain for a number of years. (269.)

4. Commercial effects of political expansion.—Mr. SNOW says that if Porto Rico, the Philippines, and possibly Cuba are to become integral parts of this country a new competition with American farmers will arise, as these islands produce to some extent products grown in this country, on which there has heretofore been a tariff. This would mean an unequal contest in tobacco and sugar. Mr. SNOW does not believe that the war in the Philippines was prosecuted for the benefit of capitalists, but, assuming that the new acquisitions are to become States, he predicts that their agricultural capabilities will be exploited by capital, which will bring the labor of the Orient into competition with labor at home. They will not be exploited by the immigration of our own people, because they are already thickly populated, and this country does not need islands upon which to colonize its surplus population, and if it did could not successfully populate tropical lands. To this belief Mr. SNOW attributes the sentiment against expansion in the agricultural districts of the West.

Mr. SNOW suggests that in framing a government for Porto Rico and the Philippines they should be left on the same basis as before as concerns their trade with the United States. He believes that if the interests of the American agriculturists were to be taken care of in framing a government for those islands, it would remove nearly all the opposition among the farmers of the country to the policy of expansion. (241-243.)

Mr. FLANDERS, Assistant Commissioner of Agriculture of New York, says that the annexation of territory may have some minor adverse influence on agricultural interests, but the result will not be injurious upon the whole. Annexation will open a large market for American goods and give work for a number of people, and agriculturists will profit with the rest of the community. (995.)

Mr. STEVENS, Commissioner of Agriculture of Georgia, believes Georgia would receive large benefits from the opening up of markets in the insular possessions and in the Orient. The United States will eventually produce 20,000,000 bales of cotton, and the more markets the better off the people will be. (916.)

E. Proposed agencies for developing foreign trade.—**1. Government inspection of exports.**—Mr. HAMILTON believes that the introduction of our products into foreign countries must be accomplished by having a rigid inspection of the articles exported, so that inferior goods can not be sent abroad. We need to protect our best exporters by requiring that goods going abroad shall be of a certain quality, or at least that the quality shall be marked upon them. Canada is sending guaranteed goods to England and Europe, taking away the dairy market the United States should have. (367.)

Dr. SALMON, Chief of the Bureau of Animal Industry, considers it desirable that the Secretary of Agriculture should be authorized to inspect and certify pure, high-grade dairy products for export. The American butter and cheese trade has been greatly damaged by the shipment of adulterated low-grade butter and filled cheese for high-grade products. (746.)

Mr. Snow believes that Secretary Wilson has done a magnificent work in promoting the exportation of butter, and that he should be authorized to have such goods inspected and branded before they are shipped. Mr. Snow considers the results to the export trade of the inspection and branding of meat products intended for export so entirely satisfactory, in removing the former prejudice against American meat and in increasing the American export trade, that it would be wise to increase the field of inspection. The Bureau of Animal Industry might well be authorized to inspect all dairy products offered for export, and to brand them for what they are. The inspection might be extended to a number of other products. The German Government has raised objections to the importation of American apples on the ground of the danger of importing the San Jose scale. If this prohibition were carried out, as part of the agrarian movement, it would amount to cutting off a very considerable part of the foreign market for American fruit, but if the exports were honestly inspected by Government inspectors the ground for the prejudice would be removed. (236.)

Mr. Hitchcock believes that there should be a system of Government inspection for dairy products similar to that applied to meat exports. Secretary Wilson, in a recent report, has recommended that such a system be established, requiring export butter, cheese, and milk to be subjected to official inspection, and that coming up to a certain standard grade certified to by the inspector as a guaranty of its quality to the foreign importer. Mr. Hitchcock thinks this would meet with the approval of the dairying industry. The general feeling, so far as tested, seems to be in favor of Government inspection for these products.

Mr. Hitchcock is strongly in favor of official inspection of export butter as the most feasible plan for preventing the shipment of an inferior product and developing an export trade in butter. The foreign importer would naturally demand butter bearing the Government certificate, and inferior butter would be at a great disadvantage. Government inspection would be particularly valuable, also, in the case of cheese. Filled cheese would probably be at such a great disadvantage without a certificate that it could not maintain its market. The inspection would probably be in part at the factory, as the meat inspection is in part at the packing house. (673-676.)

Optional Government inspection of grain.—Mr. HITCHCOCK is not prepared to say that it is at present necessary for the Government to take the matter of grain inspection entirely into its own hands, but thinks it might be well to place the inspection under the general supervision of the Government, so that uniform rules could be enforced, or for the Government to begin by establishing an official inspection optional with the exporter, as has been recently done in Argentina. He believes that the advantages of the Government certificate would soon lead to its being demanded by foreign buyers, while there would be considerable opposition to compulsory official inspection. There is not as much need for Government inspection as there was in the case of meat, because there are not the same sanitary reasons for it, and the present grain inspection system is fairly good. Mr. Hitchcock thinks that cereals with a Government certificate would command a better price in Europe, however. (680, 681.)

2. Experimental shipments of butter.—Mr. HITCHCOCK does not think it will be necessary for the United States to do all that the Canadian government has done. He believes that if the trade can once be given a fair start and the American producer convinced that there is a profit in it, the producers themselves will take the necessary action to get the required transportation facilities. But it is necessary to show that there is a possibility of establishing such a trade on a profitable basis.

"The initial experiments can very properly be made by the Government, and in fact they are in a small way now being inaugurated. The United States Department of Agriculture, by direction of Secretary Wilson, has been making experimental shipments of butter during the last 2 or 3 years, and with considerable success. We began in 1897 to send high-grade American butter in small lots to the British market."

The butter was put up in the form thought to be best suited to the requirements of the British market, the butter preferred in that market being a mild butter, lighter in color than ours, and with less salt. It was packed in a variety of packages experimentally, and as a result of the experiments of the first year the Department adopted a box similar to the cubical Australian box, but tapering slightly from top to base, in order to facilitate the unpacking. The trial exports have been continued, some shipments going to new destinations. The shipments were sent first to London, then to other English cities and to Paris, and more recently to some extent to the Orient. The result has been highly satisfactory. British butter merchants have been convinced that a high grade of butter can be made in the United States, equal to the best butter imported from other countries. That was the chief object of the experiment, which will probably be extended. (677, 678.)

3. Consular service.—Mr. SNOW says the enormous increase in our manufacturing ability within the last few years has made it necessary to look more and more to foreign markets for manufactured as well as for agricultural products, and makes it important that the consular service should be improved. When we had little or nothing to export it made little difference what kind of a consular service we had, but now that the markets of the world are being sought the consuls must be in effect commercial travelers or commercial agents for the United States. There have been a number of consular agents who have done a great work in exploiting American products abroad, but as a whole the consular service has never been as successful as it would be if men familiar with trade conditions were substituted for the consuls appointed for political reasons. The examination system has been instrumental in bringing about an improvement of the service and the consuls are showing decidedly more interest in introducing agricultural products abroad than heretofore. Mr. SNOW believes the consular reports show that there is an opportunity for a large increase in American exports. (240.)

4. Traveling agents.—Mr. HITCHCOCK does not think it possible for consular officers to render the same kind of service that could be had from traveling agents. The course of trade can not be satisfactorily investigated by a man confined to a single place, as a consul is. The consular officers are necessarily engrossed much of the time with routine business, and can not always take the time necessary to make a thorough investigation of all special inquiries sent them. Moreover, the consul represents the United States trade interests as a whole. His attention is necessarily divided, and the Department of Agriculture's requests may have to wait until those from other sources are attended to. Mr. Hitchcock feels that we can never expect from the consular service, however much it may be improved, such results as other countries are getting from the employment of agricultural experts in foreign countries. He says the consular service is supplying a great deal of valuable information to American exporters, but he has been impressed with the importance of adopting some additional measures, such as are taken by the countries with which we compete. Sending abroad special agents to study foreign markets he believes to be the most feasible way of getting the information wanted, and he considers it very important to have such men abroad, working under the supervision of the Department of Agriculture. Canada and the Australasian colonies sent agents to Denmark to gather information as to the best methods of shipping dairy and other produce, and now that Canada is beginning to compete with Denmark the Danes are sending agents to Canada to see if there is anything in the Canadian methods of production and exportation that would be an improvement upon their own. In order to get a fair idea of a country's export trade it is necessary to travel over the country. (686, 689.)

5. Agricultural attachés.—Mr. HITCHCOCK is also in favor of appointing agricultural attachés to the American embassies in some of the most important countries. The experience of the Government in one such case was eminently successful. Dr. Stiles was stationed at Berlin as an agricultural attaché, and although nominally a diplomatic official, he was paid by the Department of Agriculture and was under the direction of that Department. He traveled about over Europe as occasion seemed to demand, investigating matters affecting our agricultural export trade. His work was of great advantage to the Department. Mr. Hitchcock believes that a few such attachés could be of great service to our agricultural interests, their diplomatic status giving them certain advantages over other agents.

There are several cases where agricultural attachés have been appointed by other nations. Baron Herman was appointed by the German Government as agricultural attaché to its embassy in the United States, and with his expert knowledge of agricultural matters he renders most valuable services to the German Government. A similar attaché has recently been appointed by the Austro-Hungarian Government as an agricultural expert at Washington. (686, 687, 689.)

6. Exhibits.—In order to break down the barrier of national prejudice and ignorance, Mr. HANLEY advocates the establishment of permanent exhibits of all the natural and manufactured products of this nation in every large city in countries from which concessions can be obtained, and the publication of advertisements and descriptive articles in the native newspapers and magazines. He says that the various European nations are most liberal in their expenditures for this kind of advertising, and have, as a result, secured a strong foothold in China and adjoining countries. Mr. Hanley also believes that the United States should say "hands off" to the powers which are seeking the partition of China, and thus earn the gratitude of the Chinese nation and secure the commercial advantages of a favored nation. (292.)

It also occurs to Mr. HITCHCOCK that a great deal can be done for our export trade through the various expositions which are held all over the world. He believes it would be profitable for the Government to take even greater measures than in the

Mr. Snow believes that Secretary Wilson has done a magnificent work in promoting the exportation of butter, and that he should be authorized to have such goods inspected and branded before they are shipped. Mr. Snow considers the results to the export trade of the inspection and branding of meat products intended for export so entirely satisfactory, in removing the former prejudice against American meat and in increasing the American export trade, that it would be wise to increase the field of inspection. The Bureau of Animal Industry might well be authorized to inspect all dairy products offered for export, and to brand them for what they are. The inspection might be extended to a number of other products. The German Government has raised objections to the importation of American apples on the ground of the danger of importing the San Jose scale. If this prohibition were carried out, as part of the agrarian movement, it would amount to cutting off a very considerable part of the foreign market for American fruit, but if the exports were honestly inspected by Government inspectors the ground for the prejudice would be removed. (236.)

Mr. Hitchcock believes that there should be a system of Government inspection for dairy products similar to that applied to meat exports. Secretary Wilson, in a recent report, has recommended that such a system be established, requiring export butter, cheese, and milk to be subjected to official inspection, and that coming up to a certain standard grade certified to by the inspector as a guaranty of its quality to the foreign importer. Mr. Hitchcock thinks this would meet with the approval of the dairying industry. The general feeling, so far as tested, seems to be in favor of Government inspection for these products.

Mr. Hitchcock is strongly in favor of official inspection of export butter as the most feasible plan for preventing the shipment of an inferior product and developing an export trade in butter. The foreign importer would naturally demand butter bearing the Government certificate, and inferior butter would be at a great disadvantage. Government inspection would be particularly valuable, also, in the case of cheese. Filled cheese would probably be at such a great disadvantage without a certificate that it could not maintain its market. The inspection would probably be in part at the factory, as the meat inspection is in part at the packing house. (673-676.)

Optional Government inspection of grain.—Mr. HITCHCOCK is not prepared to say that it is at present necessary for the Government to take the matter of grain inspection entirely into its own hands, but thinks it might be well to place the inspection under the general supervision of the Government, so that uniform rules could be enforced, or for the Government to begin by establishing an official inspection optional with the exporter, as has been recently done in Argentina. He believes that the advantages of the Government certificate would soon lead to its being demanded by foreign buyers, while there would be considerable opposition to compulsory official inspection. There is not as much need for Government inspection as there was in the case of meat, because there are not the same sanitary reasons for it, and the present grain inspection system is fairly good. Mr. Hitchcock thinks that cereals with a Government certificate would command a better price in Europe, however. (680, 681.)

2. Experimental shipments of butter.—Mr. HITCHCOCK does not think it will be necessary for the United States to do all that the Canadian government has done. He believes that if the trade can once be given a fair start and the American producer convinced that there is a profit in it, the producers themselves will take the necessary action to get the required transportation facilities. But it is necessary to show that there is a possibility of establishing such a trade on a profitable basis.

"The initial experiments can very properly be made by the Government, and in fact they are in a small way now being inaugurated. The United States Department of Agriculture, by direction of Secretary Wilson, has been making experimental shipments of butter during the last 2 or 3 years, and with considerable success. We began in 1897 to send high-grade American butter in small lots to the British market."

The butter was put up in the form thought to be best suited to the requirements of the British market, the butter preferred in that market being a mild butter, lighter in color than ours, and with less salt. It was packed in a variety of packages experimentally, and as a result of the experiments of the first year the Department adopted a box similar to the cubical Australian box, but tapering slightly from top to base, in order to facilitate the unpacking. The trial exports have been continued, some shipments going to new destinations. The shipments were sent first to London, then to other English cities and to Paris, and more recently to some extent to the Orient. The result has been highly satisfactory. British butter merchants have been convinced that a high grade of butter can be made in the United States, equal to the best butter imported from other countries. That was the chief object of the experiment, which will probably be extended. (677, 678.)

10. Development of American shipping.—Mr. BRIGHAM says the building up of an American merchant marine would be of great advantage in exporting agricultural products. There are countries which know nothing of our products, but which would be glad to purchase them if they could be shipped directly from this country. (22.)

Mr. AGER, master of the Maryland State Grange, would like to see the products of this country carried in American ships. He thinks it would be better for the farmers to have the ships built in this country instead of sending the timber to Europe and having the ships built there. (115.)

Mr. HITCHCOCK has no doubt that it would be far easier to control the methods of transportation of grain if the ships were owned in America. (684.)

Mr. HANLEY says there are not sufficient ships to carry our products abroad. The National Farmers' Alliance, the National Farmers' Congress, and the National Farmers' Alliance and Industrial Union have taken action in favor of subsidizing the merchant marine. Mr. Hanley considers American ships a necessary factor in the establishment and maintenance of foreign markets, as far as the trade of the Pacific Ocean is concerned. He says the building of merchant ships is the most profitable and important industry left undeveloped in this country, and would furnish a resource for the nation in time of war. This enterprise would take from the ranks of idle labor 500,000 men, who would earn on an average \$60 a month, making a total increase in wages of \$360,000,000 annually. It would also furnish a permanent investment for about \$100,000,000, and enable American ships to earn a portion of the \$200,000,000 now paid annually to the owners of foreign vessels for carrying American people and products. Owing to the generous treatment foreign nations give their shipping, Mr. Hanley says the United States should give Government aid in starting this enterprise. Subsidizing the merchant marine would be virtually granting an export bounty on agricultural and mineral products. The competition of foreign ships would diminish the freight rates, which have been practically prohibitory, and so benefit the producer. (276, 293, 294.)

Mr. MORAN favors the reconstruction of the merchant marine, because he thinks it wrong to depend upon foreign bottoms to transport the product of American labor. He declares that the majority of farmers in the Northwest are in favor of subsidizing certain American ships according to the actual amount of the freight they carry, but opposed to the subsidy bill pending in the Senate (January, 1901). The farmers would limit the subsidy to 10 years. If it should prove a failure and of no benefit to the farmers 10 years is too long; if it should prove a benefit to the farmers, who produce 75 per cent of the freights that will be carried, there would be nothing to prevent Congress extending the subsidy. The Government should retain some control over the subsidized ships by which it could regulate freight charges, so that the ship companies could not combine to raise freights. Mr. Moran says he is in favor of any bill that will open the Oriental market and build up American shipping by giving a subsidy for the actual freight carried. He criticises certain clauses in the particular subsidy bill referred to, however, which give the benefit to fast boats which would not be able to carry much bulky freight. He says that the farmers are generally in favor of any benefit given to the Pacific steamships which carry freight. Subsidizing ships on the Atlantic would be of very little benefit to the wheat growers because they already have the European market, but if the farmers could get ships on the Pacific coast, going to the Oriental markets, they would get the benefit.

Mr. Moran says that it appeared some time ago that President Hill, of the Great Northern Railroad, was in favor of the subsidy bill, but he has been before many of the large State conventions and heard the discussions and taken part in them, and it appears that he agrees to some extent with the farmers that the bill, in its present form (January, 1901), is not beneficial to the farmers. (716, 717.)

Mr. Moran proposes two classes of compensation—one for fast ships and one for slow or freight ships—and suggests paying slow ships for the actual freight carried to foreign markets; double rates for the outward trip, but nothing for the return trip. (719.)

Mr. PROM says the farmers of North Dakota are very desirous of having an extension of their markets, and are looking to the West. Those who know of the ship subsidy bill hope it will pass, looking upon it as an instrument in the development of foreign trade. (793, 794.)

Dr. STUBBS says that the Southern Industrial Convention, after thorough discussion in which some opposition was shown, passed a resolution indorsing the ship subsidy bill. There was nothing like a fair representation of the agricultural leaders of the South at the convention, however. Most of those present were representatives of manufacturing, mercantile, and commercial interests. (783.)

Mr. TURNBULL asserts that all the raw materials for shipbuilding are found on the Pacific coast, and he expects a great development of the industry there. Iron ships built in this climate of little temperature variation need no readjustment. (881.)

11. **Export bounties.**—Mr. WEDDERBURN advocated an export bounty on staple agricultural products on the floor of the National Grange in 1896, stating that making it profitable to raise and export the staple products—cotton and tobacco for the South, and corn and wheat for the West—would stop the Southern and Western competition with the Eastern truck farmer, but that as long as a governmental system existed which aided in depressing the price of staple agricultural products it would drive the Virginia, Georgia, and Iowa farmers from their legitimate work of raising tobacco, cotton, and corn and into raising watermelons and making butter, compelling them to compete in the home market; and therefore an increase in the price of staple agricultural products would be to the advantage of the New England farmer and the truck farmer. Mr. Wedderburn still believes, as firmly as he did in 1896, that a bounty on these products would inure to the best interest of the country. (626.)

Mr. Wedderburn believes that the best system the Government could adopt would be to pay a bounty upon everything that we ship out of the country, because by shipping a surplus of products away from the United States we bring back money instead of goods. Unlike Mr. Lubin, Mr. Wedderburn has always advocated that the bounty be extended to manufactures, so as to build up American shipping. The bounty would be paid to the shipper, but the farmer would be bound to get his portion of it. The competition is so strong among the purchasers on 'Change, and transactions are made on such a close margin, that the producer would get a large proportion of the proposed bounty on anything sold on the exchanges. (627.)

Mr. Wedderburn pleads for the protection of agriculture, the greatest industry in this country, on a plane with other industries. He contends for the same opportunity for the wheat raiser that the manufacturer of steel has. If there is to be a protective tariff for the benefit of manufacturers, he favors the protection of agriculture, which can only be given by a bounty on exports. Such a bounty would not only put up the price on the product actually exported, but would raise the price in the home market. The raising of prices in the New York market 5 cents a bushel on wheat means 25 cents for every barrel of flour consumed in the United States, and the farmers are bound to get a large proportion of it. England would not put a countervailing duty on cereals, as we do on German sugar, because while we are trying to protect our sugar industry from German sugar England is striving for our wheat; she can not live without bread. (628, 630, 631.)

Mr. Wedderburn admits that the export bounty might give an impetus to the raising of more wheat in America, so that the increase in price would be lost in large part through the increased production; but he thinks it is true, as stated by Mr. Wood Davis, that the area for the production of wheat in the United States is about covered, and that we can not expect to raise very much larger crops than we have now. The Northwest is developed, and every year those lands are farmed without fertilization their productive power diminishes. Mr. Wedderburn is of the opinion that the price of wheat would be increased here, and that it would not be decreased in Liverpool, the price being fixed in Liverpool by supply and demand, and the demand exceeding the supply; but he says it would make no difference what it sold for in Liverpool if prices could be increased at home. (631, 632.)

Mr. Wedderburn says a provision for a bounty, he thinks, of about 5 cents a bushel on wheat, a cent a pound on cotton, and probably a cent a pound on tobacco was offered in Congress as an amendment, without any hope of carrying it through. Senator Cannon, of Utah, made a very strong argumentative speech in its favor, as did also Senators Tillman and McLaurin, of South Carolina, and others. Some 8 or 10 votes were cast in favor of the amendment, more than Mr. Wedderburn expected. (631.)

Mr. POWERS does not believe an export bounty on agricultural products would be of any benefit to the farmer; the result would be the same as in the case of the German sugar bounty. The English farmer, as a result of the German sugar bounty, is able to feed his hogs raw German sugar as one of the cheapest articles he can give them, and he does so at the expense of the German taxpayer. The bounty has raised the price of sugar to the consumer in Germany and thus lessened the amount consumed. If the bounty were taken away the people would consume more sugar, and thus in 20 years make a market for as much sugar as the export bounty has. Mr. Powers does not believe that the bounty has played as great a part in the development of the German sugar industry as the scientific study of the principles underlying it, which has been fostered by the German Government. (176, 177.)

XVI. ADULTERATION OF FOOD.

A. General considerations.—1. Adulteration in ancient times.—Mr. KENNICOTT, formerly city chemist of Chicago, says that Greek history has handed down the name of one who excelled in ingenious mixtures, and knew how to impart a flavor of age to new wine. In Athens there was a special inspector whose duty it was to detect and stop adulterations. Pliny mentions the adulteration of bread with white earth. Mr. Kennicott deprecates the increase of adulteration accompanying the development of commerce. (529.)

2. Extent of adulteration.—Mr. WEDDERBURN, who has for some time been employed by the Department of Agriculture in the investigation of food adulteration, believes that about 15 per cent of the whole product of food and drugs consists of fraudulent adulterations, and that about 2 per cent is injurious adulteration. He declares that this estimate, which he made for the Department of Agriculture, has never been controverted. (634.)

Mr. DYE believes that a large proportion of groceries and many other products are adulterated. The pure-food laws have been of considerable advantage, but are not always effectively enforced. (91, 92.)

3. Causes of adulteration.—Mr. GEHRMANN, director of the laboratory of the Chicago department of health, notes two chief causes of adulteration of food. Competition leads to adulteration, especially of high-priced foods. Each dealer thinks it necessary to meet the price made by his competitors, and uses such adulteration as will enable him to do it. A second important cause of adulteration is the desire to preserve goods which remain on hand unsold, and which are in danger of spoiling. (635.)

4. Effects of adulteration.—Dr. SAMUEL J. JONES, president of the National Pure Food Association, believes that sophistication of food has far-reaching effects—physical, moral, and financial. Food deficient in nutrition impairs the health and working capacity of individuals. A man who is well nourished does not depend upon artificial stimulants. The dilution of food is demoralizing to the individual dealer, impairs confidence in business integrity at home and abroad, and thus militates against the interests of the State and the nation. (525, 526.)

Professor DAVENPORT, dean of the College of Agriculture of the University of Illinois, says that the farmer feels the adulteration of food products to be injurious to him, even when he produces the materials of adulteration. Thus when wheat flour is adulterated with corn flour, though both are farm products, the farmer feels that he is damaged through the loss of reputation of American flour, and the consequent loss of export trade. (272.)

Professor Davenport says the farmers feel that adulterated foods tend to unsettle confidence and values and restrict the consumption of products. In Illinois there is a pure food association composed largely of farmers, who advocate the principle that everything should be labeled and sold for what it is. The farmers are coming to feel that they must protect their trade-marks. (271, 272.)

Mr. AARON JONES considers the prevention of adulteration and deception in the sale of food essential for the safety of consumers, who are often injured by poisonous substances, and for the protection of the legitimate producer. The demand for maple sugar, apple vinegar, pure cheese, and many other products is greatly reduced by the sale of adulterated compounds. (39, 40.)

Mr. WEDDERBURN says that the farmer has a twofold interest in the question of pure food, in that he is injured both as a consumer and as a producer. His honey, made by bees, has to compete with so-called honey made of glucose, which costs 2 or 3 cents a pound. Pure fruit jelly has to compete with jelly made from refuse, parings, and cores sweetened with glucose, and sometimes mixed with timothy seeds to counterfeit the seed of the raspberry and strawberry. Lard has to compete with mixtures of stearin and hog grease. (633, 634.)

Mr. CLOHAN says the fruit grower is very much interested in pure-food legislation. Acid vinegars have largely taken the place of cider vinegars, sham apple butter may be made of pumpkins or turnips, and other fruit products are similarly adulterated. (601.)

Mr. KENNICOTT says that allowing a poor product to be sold keeps down the production of the good product, and would eventually drive good products out of the market entirely. (533.)

Mr. HITCHCOCK, of the United States Department of Agriculture, says that the cheese exports of the United States have greatly declined since 1880, by reason of the shipping of filled cheese as full cream cheese. The inferior quality of the American product was soon detected by the customers, and our trade fell off rapidly and greatly. (676.)

CCCLVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

5. National Pure Food Association.—Dr. SAMUEL J. JONES, president of the National Pure Food Association, testifies that this association was chartered by the State of Illinois in 1897, originally under the name of the National Association of Producers and Purveyors of Pure Food, the name being afterwards changed to the National Pure Food Association. The incorporators being convinced that the dealers in food products for profit should not have any part in the management of the association, they were made eligible only to associate membership, without the right to vote or to hold office. The association memorialized Congress in favor of the bill introduced by Senator Thurston to create a pure food commission, but has not committed itself to any other particular bill. The objects of the association are to secure pure, nutritious, and economical food, and the instruction of the people how to prepare and utilize it to the best advantage. Interest in the subject has been developed through the press, by public lectures, and through farmers' congresses and other agricultural bodies. The association has sent representatives to the National Pure Food Congress, which it does not antagonize in any way. (521-527.)

B. Particular adulterations.—1. Milk.—Mr. KENNICOTT, formerly city chemist of Chicago, says a common practice of Chicago milkmen is to remove a part of the cream and sell what remains as full cream milk. The skimming takes away the larger part of the food value. (529, 531.)

Mr. GEHRMANN, director of the laboratory of the Chicago department of health, says that supervision of the quality of milk sold in Chicago was established by a city ordinance in October, 1892, and was transferred to the department of health in September, 1893. During 1893, out of nearly 9,000 samples analyzed, more than 45 per cent were below grade. The first 500 samples were taken at railway stations immediately on arrival. Of these only 41 samples, or 18 per cent, were below grade. Of the next 500 samples, taken from dealers' wagons on the street, 374, or 75 per cent, were below grade. This showed that at that time the adulteration was chiefly the work of the city dealers. In February, 1894, an increased number of samples were taken in the poorer parts of the city, and it was found that skimmed milk was extensively sold there. In 1895 the department experienced great difficulty in securing the prosecution of offenders. As a result the percentage of poorer samples increased rapidly. In the latter part of the year the department began to publish the names of those whose samples were found below grade, in the daily papers, without awaiting the results of prosecution. This policy resulted in a great improvement in the character of the milk offered. In December, 1895, the prohibition of the coloring of milk and cream caused a temporary rise in the apparent proportion of poor samples. In September, 1897, prolonged dry weather caused a milk famine, and the use of water and other adulterants to eke out the short supply was apparent in the increased proportion of poor milk. (635.)

Dr. Gehrman submits a diagram showing a diminution of the per cent of milk samples found below grade in Chicago from 49 per cent in February, 1894, to about 2 per cent in 1897, with some temporary fluctuations due to special causes. (635, 636.)

Mr. KENNICOTT says that milk robbed of part of its cream is made to look rich by coloring with annatto or with aniline dyes. It is an unsettled question whether some of these dyes are injurious to health or not. Very little pure milk is sold in cities. Boston probably has the best milk in the country. In Boston, for a part of the year, the standard of milk requires 13 per cent of solids, while in Illinois milk which has 12 per cent of solids passes as pure. (531.)

Mr. AGER, master of the State Grange of Maryland, states that persons have recently been arrested in the District of Columbia for selling sophisticated cream and milk. He understands that standard cream must have 20 per cent of pure fat; some samples were found to have only 14 per cent. These samples looked as good as cream of standard richness. A yellow coloring matter had been added. Milk is sometimes colored to increase its apparent richness. A preparation of annatto is used for this purpose, as well as for coloring butter. The witness does not think it injurious to health. (116, 117.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, says that the boards of health of the principal cities of his State have recently taken up the matter of milk adulteration, and have greatly improved conditions. The adulteration of milk is easy to detect. Mr. Hamilton believes that the supply in the cities referred to is now reasonably pure. (371.)

2. Cheese.—Mr. FLANDERS, Assistant Commissioner of Agriculture of New York, says that the State of New York has for several years given instruction to its cheese makers in order that they might produce a uniform first-grade article. It has provided by statute for the issue of a brand bearing the words "New York State Full

Cream Cheese" to each factory that makes such cheese, and the agricultural department of the State prevents the fraudulent sale of filled cheese and of cheese falsely branded as to quality. The purpose has been to make the State brand a guaranty of the quality of the product. But some cheese dealers in the West, particularly in Chicago, have imitated the State brand and placed it on inferior goods. This injures the reputation of the cheese and the cheese makers of New York, and ruins the market. (995, 996.) (See also Wieting, 994.)

Mr. FLANDERS says that the New York State full cream cheese brand can not be protected under the patent or trade-mark or copyright laws. The person who registers a trade-mark must have a proprietary interest in it, and the State has no such interest in the cheese produced within its borders. Each proprietor of a cheese factory might file his particular brand, but the expense would be too great; the cost of filing the trade-mark would be \$25, and there would be the additional cost of protecting it in the courts. (996.)

3. Flour and corn meal.—Mr. KENNICOTT, former city chemist of Chicago, says that he does not know whether flour is adulterated with corn flour in Chicago or not. A friend of his has examined samples of flour without finding corn flour. (532.)

Mr. SNOW, statistician of the Orange Judd Farmer, says that the mixed-flour law of Congress has resulted in the almost entire abandonment of the mixing of wheat flour with corn flour. (237.)

Dr. SAMUEL J. JONES has been told of a miller who regulated the dilution of his corn meal by the customer's promptness of payment; if he was prompt, he got corn meal; if doubtful pay, he got a certain percentage of corn cob; and if very doubtful, he got a very large proportion of cob and very little corn. (527.)

4. Maple sugar and sirup.—Mr. SPEAR does not know of any adulteration of maple sugar in Vermont. The law of the State is very strict against it, and would be sharply enforced. Only about 10 per cent of the genuine Vermont product is sold in the form of sirup; the remainder is sold as sugar. So far as the sugar is not sent to special customers a large part of it goes to sirup houses outside of the State, where it is mixed with glucose and cane sugar and sold as pure Vermont maple sirup. The maple sirup found in the markets is a combination of about 20 per cent of the purest grade of maple sugar with glucose and cane sugar. This adulteration not only lowers the price of the honest goods, but discredits them with the consumer. Mr. Spear considers the labeling of such a combination "Vermont maple sugar" as much a counterfeit as counterfeit money. The consumer pays nearly the price of pure goods, and the producer of honest goods suffers. (408, 409.)

5. Olive oil.—Mr. KENNICOTT says that cotton-seed oil is as good food, or very nearly as good, as olive oil. He has used cotton-seed oil as a salad oil, knowing what it was, and he likes it just as well as olive oil. (533.)

6. Cream of tartar.—Mr. KENNICOTT says that cream of tartar is sold in Chicago which does not contain any cream of tartar whatever, but consists of soda calcium phosphate, similar to phosphate rock that is sold as a fertilizer. There is nothing unclean about it. The witness has found as much as 55 per cent of plaster of paris in cream of tartar. It was impossible to say whether it was added as plaster of paris or was produced in the manufacture of the soda calcium phosphate. The plaster of paris would be simply inert matter in the stomach. (533.)

7. Coffee, spices, and drugs.—Mr. KENNICOTT showed samples of ground coffee which contained dried grain, and samples of artificial coffee beans, unground. He also showed "fillers" for pepper, cinnamon, cayenne pepper, nutmeg, mustard, all-spice, and cloves. These fillers are composed of dried and pulverized grain. Ground buckwheat hulls are sometimes used to imitate black pepper. Similar substitutes are also extensively used for filling drugs. Fillers are made to resemble in appearance the spices or drugs with which they are to be mixed. These adulterations are not directly injurious. (530.)

8. Beer.—Mr. KENNICOTT states that he has never found anything particularly injurious in beer, although he has been told and has read of adulterations which are undoubtedly injurious. Some of the foreign beers have been colored with picric acid. Much beer is made with impure water, and this is a kind of adulteration. (532.)

9. Canned goods.—Mr. KENNICOTT says that canned pease are colored green with copper. (530.)

10. Restaurant foods.—Dr. SAMUEL J. JONES testifies that the proprietor of a Chicago restaurant brought a pie to a chemist of that city to be analyzed to determine what filling his competitor used in order to undersell him. The result of the analysis led the chemist to analyze other articles of restaurant food, and after doing so he came to the conclusion that he had taken all the down-town lunches he cared to, and that he would carry his lunch. (525.)

CCCLVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

11. Uncleanliness in preparing food.—Mr. KENNICOTT mentions the making of filthy foods, which may be unintentional, as being of the same nature as adulteration. He exhibited a piece of bread with a young rat baked in it. He also showed a piece of candy bought in a department store, which was dusted over with flour and appeared to be in a good condition, but which was found extremely filthy when the flour was removed. (530.)

12. Stock foods.—Mr. M. F. GREELEY, of South Dakota, complains that there are millions of dollars' worth of stock foods sold which are of very little value. The agricultural papers seem to be afraid to say what they think on the subject, possibly in some cases because the proprietors of the foods advertise extensively; and many of them do not know how little value there is in some of the foods. Mr. Greeley says the experiment stations ought to take up the question, as a few Eastern stations have, and publish the frauds. He also favors a national law on the subject, on the ground that local laws are not feared by those who violate laws. (940, 941.)

C. Oleomargarine. (See also *Oleo oil and butter*, p. CCCXII.)—1. **Extent of its use as butter.**—Mr. VAIL does not think the Vermont creameries use oleo in butter; he has never heard of a case against the creameries, and the Vermont law is very strict in that regard. (415.)

Mr. FLANDERS, Assistant Commissioner of Agriculture of New York, says that when the State agricultural department was established oleomargarine was manufactured in large quantities in New York, hundreds of thousands of pounds a year, and sold as butter. Now, none is made in the State and little is sold there; what is sold is sold clandestinely. (998.)

Mr. Flanders says that the violations of the oleomargarine law in New York are few when one considers the size of the State and the population. They sometimes result from the acts of persons outside the State. Thus a man in Buffalo was found to be selling oleomargarine as renovated butter. He claimed that he had been deceived, and it was not found possible to prove the contrary. The packages bore no marks to indicate that they contained oleomargarine. The packers had failed to comply with the United States law in this respect. The companies from which the goods had been bought were found to be "fakes," covers for the real producers. It is believed that the large manufacturers of oleomargarine, with some exceptions, conduct their business in a legitimate way. (996, 997.)

2. **Wholesomeness.**—Mr. FLANDERS regards renovated butter as by all means a more wholesome article of food than oleomargarine, "because one is a butter fat and the other is a fat that was never intended to go into the human stomach raw. It takes more effort to digest oleomargarine than it does to digest butter." He understands that oleomargarine contains 4 or 5 times as much stearin as butter, and that while good butter contains from 4 to 8 per cent of butyric acid, oleomargarine has only a trace of it. Butyric acid is an aid to digestion. (997.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, thinks that butterine made from healthy animals without the use of impure or injurious substances would not be injurious to health. (368.)

Mr. KENNICOTT, former city chemist of Chicago, regards butterine as a good food, and objects only to the selling of it as butter and at the price of butter. There is a very large legitimate market for butterine. (530.)

Mr. AGER, master of the State Grange of Maryland, does not consider oleomargarine a wholesome food; at least he would not buy it for his own use. The great objection to the trade in it, however, is the fact that it is sold for butter. "It takes the place and lessens the price of a good article." (116.)

D. Legal remedies.—1. **Existing pure-food legislation.**—*Massachusetts.*—Mr. STOCKWELL says the Massachusetts State Board of Health has appropriations to enforce the pure-food laws, and the Dairy Bureau punishes the fraudulent sale of oleomargarine. The oleomargarine law has stood the test of the highest courts and is being largely copied in other States. The food laws of Massachusetts are working well. (902.)

Pennsylvania.—Mr. HAMILTON testifies that the Pennsylvania pure-food law has done good service in clearing the shelves of grocery stores of articles of food injurious to health. It was formerly the practice of manufacturers to use preservatives, such as boracic acid and salicylic acid, which are regarded as injurious. There are some 13 inspectors whose sole business it is to secure samples, and a number of chemists whose business it is to analyze them and report to the dairy and food commissioner. Whenever the chemists report that an article is clearly a violation of the law suit is brought. The law does not reach the adulteration of goods with harmless substances. If the manufacturer marks on the package that it is a compound he may put in any adulteration not injurious to health, and the public may be deceived

in supposing that there is more of the valuable ingredient than there really is. Inert substances are not considered likely to be injurious. A certain amount of such material seems to be necessary in order to distend the stomach properly; but there may be so much put in as to make the food practically worthless. (367, 368.)

Illinois.—Mr. GEORGE testifies that Illinois has a butterine law, but not a pure-food law covering the entire ground. Even the butterine law is not what it should be. It compels the large packages to be marked, but boarding houses and hotels put butterine on the tables without notice, and people eat it without knowing what it is. (226.)

South Dakota.—Mr. GREELEY testifies that South Dakota has a pure-food law. (940.)

Kentucky.—Mr. NALL says the Kentucky pure-food law is under the direction of the Director of the Experiment Station. He is the official who sees that the pure-food law is enforced. (814.)

Louisiana.—Dr. STUBBS thinks food inspection is left to the cities in Louisiana. New Orleans has a chemist entirely engaged in the detection of impure food. (784.)

2. Character of laws needed.—Dr. GEHRMANN says that laws to promote purity of food ought to be extremely explicit as to quality and quantities of constituents. General expressions are differently interpreted by successive administrations, with the result that dealers are placed at a disadvantage and the public does not know what to expect. It is very desirable that food laws be uniform in the various cities and States. Food inspectors should be persons interested in the work, and the chief executive should have some of the qualities of the scientific man, but should be primarily a man of executive ability. Every case of adulteration should be fully tried, and political and personal considerations should be strictly excluded. Measures should be taken for educating the public in regard to requirements of the law. Finally, a penalty which dealers fear more than any fine is the publication of the names of those who sell impure food. (637.)

3. Need of national legislation.—Mr. KENNICOTT, former city chemist of Chicago, says that while some States, like Michigan and Massachusetts, have excellent food laws, and are able to diminish the practice of adulteration within their territory, not much can be done until national legislation is obtained. Goods which do not pass inspection in one State may pass in another. The great remedy is to force manufacturers to mark goods for what they are; but until we have national legislation with regard to the marking of goods nothing effective can be accomplished. (530, 531.)

Professor DAVENPORT, of the University of Illinois, is decidedly in favor of national legislation to prevent the adulteration of food. He says that the matter can not be controlled by State legislation, because strict laws in one State result in the dumping of adulterated products upon other States. He emphasizes the need of national legislation, providing that the brand on a product shall be a true index of what it is, both for home protection and for the protection of the export trade. (272.)

Mr. NORRIS says the National Grange has passed a resolution recommending pure-food legislation. He believes the United States is the only nation that has no law protecting its food products, and that adulterated products crowd out pure goods. (332.)

Mr. SPEAR says no matter of legislation is regarded with as much solicitude by the farmers of Vermont as a national pure-food law. They think it reasonable to ask maple-sugar manufacturers to put upon every package a statement as to its purity or adulteration. (408, 409.)

Mr. WIETING and Mr. FLANDERS, respectively Commissioner and Assistant Commissioner of Agriculture of New York, agree that the National Government should enact a law that no dairy or food products entering into interstate commerce may be falsely branded or labeled as to the State in which they are made. Bills to this effect have been introduced in Congress, but have not passed. They also approve the principle of the Grout bill, that whenever dairy or food products are brought into a State they should immediately become subject to the State law, even if in original packages, just as if they had been products of the State. (994, 996, 998.)

Mr. DYE considers it desirable that Federal and State legislation should cooperate in remedying the evil of adulteration, which is injurious to the producer of pure articles as well as to the consumer. Everything should be sold strictly for what it is. There should be a penalty for selling goods for pure which are not so. (98.)

Mr. COLLS, a farmer and dairyman of New Jersey, favors the enactment of a pure-food law. He says that while every man has a right to make any uninjurious article, he should sell it under its proper name. He should not manufacture oleomargarine and sell it for butter. (123.)

Mr. MILLER, secretary of the Ohio State Board of Agriculture, considers a pure-food law very difficult to enforce. Such a law should be of a national character,

COCLX THE INDUSTRIAL COMMISSION:—AGRICULTURE.

and the enforcement of it should be in the hands of the Department of Agriculture. (617.)

Mr. WEDDERBURN, master of the State Grange of Virginia, believes that there should be a national pure-food law based upon the interstate-commerce clause of the Constitution. The enforcement of it should be confided to the Department of Agriculture. (633.)

Mr. HANLEY thinks there should be a Federal pure-food law. Any agency that would establish the reliability of American goods would give them a greater market value. Everything should be branded as it goes out. The National Farmers' Alliance and Industrial Union favors a national pure-food and inspection law. (282.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, thinks that the United States ought to require all packages of food products to bear labels showing their constituents. This would prevent fraud and enable everyone to know what he was buying. Such a law would have to be national to be effective. The States could, however, have an analysis made to determine whether the contents of the packages corresponded with their labels. (371.)

Mr. NALL, Commissioner of Agriculture of Kentucky, is inclined to believe that pure-food legislation should be National rather than State, the rights of citizens of one State to do business in another State being so mixed up that sometimes protection is not found in State laws. In regard to drugs and food products generally other than agricultural products, Mr. Nall sees no reason for putting the execution of the law in the Agricultural Department. (814.)

Dr. STUBBS says there is quite a favorable sentiment among the farmers of Louisiana for a national pure-food law. They would prefer a national to a State law, because recent decisions in whole-package cases frustrate the State laws to a large extent. Dr. Stubbs would give the national Department of Agriculture the execution of the law. (784.)

Mr. GREELEY, secretary of the Board of Regents of Education of South Dakota, hopes that the Government will take hold of the subject of the adulteration of foods and drugs. (940, 941.)

Mr. MCKAY, a trustee of the University of Illinois, thinks there ought to be national pure-food legislation, for State laws are too desultory and conflicting to be very effective. The matter should be under control of the United States Department of Agriculture. Mr. McKay suggests that a special appropriation be made by the National Government to each of the experiment stations for carrying on investigations on the subject of pure food. (534.)

Mr. WILSON, master of the Illinois State Grange, favors a national pure-food law. (254.)

Mr. CLOHAN, of West Virginia, favors Federal pure-food legislation. He thinks pure-food legislation should be general and apply everywhere; otherwise there is nothing to hinder grocers in Pennsylvania or other States having pure-food laws when they get something that will not pass inspection from dumping it into West Virginia, where there is no such law. Mr. Clohan would lodge the execution of the pure-food law in the Department of Agriculture, or perhaps in the Department of Justice, as everyone is interested in the matter. (600, 601.)

Mr. SNOW testifies that pure-food legislation has been widely discussed at meetings of farmers' organizations, and that they all favor it. The antagonism to pure food legislation has grown out of the unwillingness of manufacturers to submit their business to public inspection. There have been organizations among manufacturers to postpone pure-food legislation. (237.)

Mr. GEORGE favors a national pure-food law to protect the consumer as well as the producer of farm products. (226.)

Mr. POWERS advocates Federal legislation providing for the inspection and guaranty of articles of interstate and international trade. He says there is loss to the American farmers from the fact that some of our corn shipped to European ports, though warranted by certain export cities, reaches there in an unmerchantable condition, the loss of foreign dealers reacting to the detriment of American exportation. The Government should find out what places are thus permitting the issue of valueless certificates, and should seek to protect the good name of American farm products in the markets of the world. In the case of meat products he thinks the inspection is well conducted by the Bureau of Animal Industry. (192.)

Dr. SAMUEL J. JONES, president of the National Pure Food Association, thinks the better element of manufacturers, who wish to be honest but are driven to the sophistication of foods by competition, would welcome relief from this state of affairs. He believes that it is the duty of venders to let people know what they are getting and paying for, and that the law should secure this. In his opinion the most natural place for conducting the inspection and control of food would be the United States Department of Agriculture. (527-529.)

4. Proposed legislation against oleomargarine.—Mr. BRIGHAM believes that the tax on oleomargarine should be increased. There is no injustice in the sale of oleomargarine as such, but most people believe they are buying butter. The pure-food laws of the various States have been of great advantage to the consumer and to the farmer, but officers are under strong temptation not to enforce them effectively. Legislation to warn the foreign purchaser as to the character of goods he buys would also be advantageous to the American farmer. (22-27.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, thinks that the United States ought to put a tax of 10 cents a pound on oleomargarine, "so as to raise the price of it so that it can not undersell butter in the same market." It costs about 7 cents to manufacture. The dealer gets 18 or 20 cents for it. This leaves so large a profit after paying the present 2-cent tax that the temptation to fraudulent substitution is very great. If the tax were 10 cents the profit would be so small that it would hardly pay to take the risk of evading the State laws. (370, 371.)

Mr. AGER would have a heavy tax put upon oleomargarine, and he would also have it colored pink instead of yellow. Mr. Ager states that there is very little butter which is not colored. He does not consider the coloring matter injurious to the health. He does not suppose that any of his auditors would use winter butter in its natural whiteness in preference to the colored article, even with knowledge of the artificial coloring. (116, 117.)

Mr. BACHELDER believes that any product which is not made strictly from milk and cream should be so distinguishable or so marked that all persons using it shall know that it is not pure butter. The present laws often require labeling by which the purchaser is notified, but the actual users in hotels, boarding houses, etc., generally suppose that it is pure butter. The witness has secured 32 prosecutions within one month for the violation of the New Hampshire law requiring hotels, etc., to notify their guests that oleomargarine is used. There is no objection to the sale of oleomargarine under its own name and character. (45.)

Mr. Bachelder advocates a tax of 10 cents a pound on oleomargarine colored in imitation of butter.

Mr. GREELEY, of South Dakota, says oleomargarine should be made to sail under its own colors, just as other foods and drugs should. Many prefer properly made oleomargarine, as it is possible to have it much cleaner than butter, because it is hard to keep milk clean. Mr. Greeley thinks no very severe oleomargarine law can ever be enforced. (945.)

Mr. STOCKWELL, secretary of the Massachusetts State Board of Agriculture, favors the Grout bill, feeling that oleomargarine is a fraud upon the dairy interests of the country which should be abated. The manufacturer of oleo should, at any rate, use some distinguishing color, so that it might be sold upon its merits.

Mr. Stockwell also favors the Brosius bill. (902.)

Mr. NORRIS says there is a good oleomargarine law in New York which is very well carried out, and that it should be extended throughout the whole country. (332.)

Mr. BUDGE, of North Dakota, thinks some way should be provided by which people should know what they are getting. Oleomargarine should be branded for what it is. (857, 858.)

XVII. FARMERS' ORGANIZATIONS.

A. Purposes, extent, and results.—1. **Ideas underlying the organization of farmers.**—Professor DAVENPORT, of the University of Illinois, believes that the original idea resulting in the organization of farmers was the need of protection. A wave of sentiment went over the country to the effect that everything must be organized. Among farmers there was a strong objection to middlemen, and in many sections the Grange was organized with that idea principally in mind. The Grange stores were not successful, as a rule, but farmers learned something about retail prices, and found that a profit of 25 per cent on dry goods, for example, was not very big pay. (268.)

Mr. BRIGHAM, Assistant Secretary of Agriculture, says that the National Grange and other farmers' organizations have been forced into existence by the combinations in other lines of industry, by railroad discrimination, etc. The first purpose of these farmers' organizations was to protect their financial interests, but later they sought to improve the social and intellectual condition of the agricultural classes. The organizations are not less active than in their earlier days, but are somewhat more conservative, undertaking to discuss thoroughly each proposition and to push it through. (18, 19.)

Mr. Brigham says there is no business that requires more general intelligence than farming. Moreover, the attractiveness of the farm can be greatly increased by educating the farmers. To this end the farmers' organizations are endeavoring to introduce educational, literary, and social advantages of various kinds. They aim to have an organization in every township. (8.)

CCCLXII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. BROWN, president of the Georgia Agricultural Society, urges especially the necessity of organization among farmers to protect their interests and to educate them. Most farmers, especially in the South, think little about their business, and this in part explains their failure to diversify agriculture. (69, 70.)

Mr. GEORGE, of Chicago, enumerates five general organizations of farmers—the Farmers' Alliance, the Farmers' Alliance and Industrial Union (the Southern branch of the organization), the Farmers' Mutual Benefit Association, the Patrons of Industry, and the National Grange, Patrons of Husbandry. The farmers were organized for social and intellectual culture mainly, and for cooperative effort. Mr. George thinks the effect of organization has been very good. The Granger laws and perhaps the butterine law resulted from the organization of the Grange. The Farmers' Alliance assisted in securing legislation concerning butterine. These orders were all nonpartisan in the first place, their constitutions precluding partisanship, but they did not hold to that idea except theoretically; practically they became political parties, and in that way have failed. The declaration of principles of the Farmers' Alliance was practically used as a platform for the People's Party. The Grange, which perhaps stands at the head of these organizations, has steered clear of partisanship during the last 25 years. (222.)

Dr. CROWELL says the Grange movement, the Farmers' Alliance of the South, the Wheel in the central South, and almost all agricultural organizations have been called into existence by the necessity of explaining why the farmer was getting so small a proportion of what the consumer paid for farm products. It has been necessary to look at the relation of agriculture to the distributive system and the world market. (337.)

Mr. WILSON, master of the Illinois State Grange, thinks farmers should be organized for the discussion of matters of common interest, both as to the best manner of cultivation and such great economic questions as transportation, foreign markets, etc. (250.)

2. Farmers' organizations in various States.—Massachusetts.—Mr. STOCKWELL testifies that there are in Massachusetts 34 agricultural societies represented on the Board of Agriculture, 9 horticultural societies, 16 farmers' and mechanics' clubs and associations, 24 farmers' clubs, 16 Pomona and 158 subordinate granges, as well as the State Grange, and 18 agricultural organizations of a miscellaneous nature. Mr. Stockwell thinks the improvement in agricultural methods has come very largely from these organizations. (893.)

Ohio.—Mr. MILLER says there are various farmers' organizations in Ohio, the Grange being, perhaps, the leading one in numbers and influence. (613.)

North Dakota.—Mr. BUDGE says there are not very many farmers' organizations in North Dakota. The Grange and the Farmers' Alliance have gone to pieces. The people do not seem to take much interest in the grain-growing associations, and there are very few farmers' clubs. The Farmers' Alliance ran into politics and Populism; the leaders ran it to benefit themselves. (851.)

Mr. PROM, of Milton, N. Dak., says there is now no organization among the farmers of that district. There was one once—the Farmers' Alliance, originally started for discussing agriculture for the benefit of farmers—but it turned into a political association and went to pieces. (792.)

South Dakota.—Mr. JUMPER says there are no grain growers' associations, alliances, or granges in the northern half of South Dakota. They have all gone out of existence. (737.)

Mr. GREELEY, of South Dakota, does not believe in the organization of farmers, as a rule, his particular reason being that organizing tends to eliminate individuality and independence. He thinks clubs and associations in the country are apt to have too many rules and regulations. In South Dakota the organizations have been drawn into politics. The farmer can not think as sharply as the politician, who has nothing but politics to think about and will "work" these organizations, even though they swear they will have no politics in them. Mr. Greeley is glad to note a growing tendency among the best farmers of his section to depend more upon themselves and less upon organizations and legislation for success. In some parts of South Dakota there are a few small farmers' clubs. (937, 938.)

Virginia.—Mr. WEDDERBURN says there are practically no organizations of farmers in Virginia. The Grange was very largely organized at one time, but it got into politics and broke up; though an attempt was made to keep it up for a number of years, it is practically out of existence. The Farmers' Alliance went the same way, but a little more quickly. The Horticultural Society and farmers' clubs here and there are practically the only organizations keeping up an existence in the State. There are several very fine farmers' clubs. Mr. Wedderburn mentions in particular the Woodlawn Club, in Fairfax County, composed principally of New Jersey Quakers, who

migrated to Virginia before the war and bought some of the original Mount Vernon estate. He characterizes them as thrifty, intelligent, industrious, and successful farmers. (624.)

West Virginia.—Mr. CLOHAN says the Farmers' Alliance was very short lived in West Virginia. It went into politics, and was apparently of no value to anyone. The idea of the Alliance was to be a great political party and get the offices. (600.)

Kentucky.—Mr. NALL testifies that there are numbers of organizations among the live-stock breeders in Kentucky, and recently he has endeavored to get farmers to organize county clubs, showing that it would be of great assistance to the State Department of Agriculture if they would do so. (811.)

North Carolina.—Mr. WHITE testifies that there are granges, agricultural societies, and farmers' alliances in North Carolina, but colored men are not admitted to them unless they form separate organizations. There were a good many colored alliances until the organization came into disrepute by getting into politics. The Farmers' Alliance of North Carolina drifted into the Populists, who made an alliance with the Republicans. There is a statute prohibiting political organizations of a secret character, and as the Alliance meetings are secret they could not be kept up. Among the colored tenant farmers there is little or no organization or meeting for the discussion of agricultural methods. (424, 425.)

Mr. GRAHAM, president of the Farmers' Alliance of North Carolina, testifies that the Alliance in its palmy days was a great benefit to the farmers in that State; it nearly broke up the lien system. The Alliance borrowed money and bought goods and sold them at cash prices, reducing the price of flour and other articles one-half. In this way the farmers got on their feet, and the mortgaging of crops to-day is much less prevalent than formerly. Unfortunately politics got into the Alliance, but Mr. Graham looks for a reorganization with politics eliminated. He estimates that the membership in North Carolina is between 5,000 and 6,000. (437.)

South Carolina.—Mr. HAMMOND, a cotton planter of South Carolina, says that both the Grange and the Farmers' Alliance have existed in his region, but they have passed away. (829.)

Georgia.—Of farmers' organizations in Georgia Mr. HALE says:

"At one time the Grange and the Farmers' Alliance were both there, but both tumbled into politics and thought they were going to benefit agriculture entirely by legislation. They began at the wrong end. If they had made them educational institutions for the farmer and taught them to mind their own business and become better business men they would have succeeded better."

There are now no permanent organizations covering the whole State except the State agricultural and horticultural societies. Mr. Hale does not believe that either the Alliance or the Grange has a subordinate organization in the State. There are some local organizations. (390, 391.)

3. Benefits of organization.—Dr. CROWELL says organization has raised the farmer's standards of living and of profit by improving his purchasing power. He has become a more intelligent purchaser, and organization has given him a larger view of his function in the community. He has come to feel that the agricultural interest is so intimately connected with all other economic interests that he must maintain a high standard of living in order to preserve his social efficiency. To some extent organization has prevented the migration of young men from the farm by giving them association and opportunity for leadership. (337.)

Mr. KERCHUM thinks farmers' organizations have been of great benefit. The farmers' organizations in New Jersey have been the means of disseminating information and have been of advantage in the purchase of fertilizers and other supplies. (135.)

Mr. COLES says there are always benefits resulting from an organization if it is carried on properly. It gives the members ideas and protection and they can cooperate to a certain extent, though farmers do not cooperate as well as men in many other occupations. (126.)

Mr. NORRIS believes that the great need of the agriculturist is organization and a more intelligent knowledge of the affairs of the country and of his own business. He is informed by an institute worker that wherever the Grange or farmers' clubs have a firm hold in New York State the farmers are more progressive than in other counties. Mr. Norris does not urge the organization of the Grange on the ground of its financial benefits as much as for its educational and social benefits. The great social benefit of the organization is that it brings all the members of the family into one order where farm and household matters are discussed. It opens up a new avenue of thought to the farmers' wives and creates a better feeling among the farmers. (329.)

Mr. BRIGHAM says that organizations have been very beneficial in protecting the farmers' against unjust combinations to force down prices of agricultural products or to put up prices of goods bought by the farmers. Mr. Brigham refers especially to one case where wool buyers sought to fix the price in Ohio at 25 cents. The State

CCCLXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Grange, by a circular to farmers to hold back their wool, kept the price above this figure.

It was formerly impossible for farmers to buy agricultural implements directly from the manufacturer. They had to pay an exceedingly high profit to middlemen. The various organizations have done much toward ascertaining the first cost of such implements and securing arrangements for buying them directly, if desired. By means of such arrangements the middlemen have been forced to content themselves with reasonable profits. The witness speaks also of a case where his organization was successful in preventing Arbuckle Brothers from refusing to sell their coffee to dealers who disposed of it at less than the fixed manufacturer's price. The attempt of the National Cordage Company to put up the price of binder twine from 10 cents to 25 cents was also checked by the refusal of the farmers belonging to organizations to buy any twine whatever. (18-20.)

Mr. DYE believes that the organization of farmers is of great advantage in enabling them to cooperate in buying goods in large quantities, especially fertilizers and groceries. It also helps them to cooperate in selling goods, thereby reducing the cost of transportation and the expenses of middlemen. Organization also improves the condition of the farmer generally, increases his intelligence, etc. (94.)

Mr. WILSON testifies that the Patrons of Husbandry have effected some good legislation, both State and national. They secured the railroad legislation known as the Granger laws of Illinois. He refers also to the oleomargarine law, pure-food legislation, and the raising of the Commissioner of Agriculture to a Cabinet position, and says the organized farmers are entirely responsible for free rural mail delivery; also that it was largely through the Grange that the interstate commerce law was passed. Not a railroad in Illinois obeyed the law reducing the passenger traffic from 4 to 3 cents until the farmers carried it to the Supreme Court and won the case.

Dr. CROWELL thinks that, in spite of the failure of the Potter law to reduce railroad rates, the influence of farmers' organizations on transportation has been helpful. (337.)

B. Particular organizations.—1. Patrons of Husbandry.—Mr. JONES, master of the National Grange, states that the fundamental purpose of the Patrons of Husbandry is to elevate and improve the agricultural classes, socially, intellectually, morally, and financially.

There are between 27,000 and 28,000 Grangers in the country. The membership in a local grange is not allowed to fall below 13. The largest number in any one local organization is 607. Aside from these subordinate bodies there is the county or Pomona Grange, the State Grange, composed of representatives from county and local granges, and a National Grange, composed of the masters of the State granges.

One of the chief purposes of the order was to institute a harmonious spirit among the farmers of different sections. This it has largely accomplished. Locally also its social advantages have been of inestimable value. Farming by its very nature tends toward too much isolation. The Grange has done much to promote harmony among individuals, social enjoyment, and refined usages. A majority of the attendants at the local meetings are women, who appreciate highly the advantages offered.

From an educational standpoint the organization has improved the public-school system in the country districts everywhere, and is now insisting that agricultural science be taught in the schools. At its meetings themes relating to agriculture, domestic and political economy, and the duties of citizenship are discussed. After men and women have been in the order for a year, fully 95 per cent of them take part in the educational features. The organization also makes efforts to beautify the roads and homes. It aims to increase the attractiveness of farm life, insisting on the value of the farm as a home, and not merely as a source of income. In this way it has kept the value of farms from decreasing. (29, 30.)

Mr. JONES says the National Grange is not partisan, but it does seek legislation of various sorts in the interests of farmers. It has legislative committees in every State, but its members realize that the farmer can not be favored beyond his just deserts without injury to others, and that injury to others reacts on the farmer. The organization expects much from the work of the Industrial Commission, and believes that it should be perpetual. It is prepared to cooperate with the commission in any way. (30, 31.)

Mr. BRIGHAM says the National Grange is steadily increasing in strength. It was founded in 1866, but had little growth until 1872. It now includes about 28,000 organizations, and has gained in membership probably 100,000 during the past 10 years. It does not enter party politics, but endeavors to secure various political reforms, such as direct election of senators, and to educate its members politically. The results accomplished in this direction have been very encouraging. (20, 21.)

Mr. AGER, master of the Maryland State Grange, says that the Grange was organized for social, educational, and financial benefits. The educational feature was considered especially important, and he thinks the greatest benefit of the order is educational. The members must be engaged in agriculture or in occupations which do not conflict with it; clergymen and school teachers are admitted. The State of New Hampshire has 21,200 members in more than 200 granges, but the order is not generally prosperous in the South. There was at one time a strong organization in Maryland, but it has been materially reduced. Many were disappointed because it did not assume political features, and many others expected it would put money in their pockets without any effort on their parts. At each meeting questions are selected for discussion at the next meeting, and papers are read on those questions. Any question of interest to agriculturists is acceptable, but partisan politics and sectarian religion are excluded. Professors from the Department of Agriculture and from the Maryland Agricultural College are often invited to the county meetings, which are held quarterly. The order has National, State, county, and local organizations. National and State convocations are held annually. Mr. Alger thinks the grange has been beneficial in making better farmers and better citizens, and that the social feature is of much value. Members make many acquaintances, and there is a beneficial fraternal feeling existing in the order. The Grange holds to the principle of doing business for cash, maintaining that it is better to hire money and pay interest than to go in debt. (113, 114.)

Mr. CLOHAN says the Patrons of Husbandry have been in existence at least 25 or 30 years in West Virginia, and the farmers connected with the organization have improved their methods of farming and of buying and selling. Within 4 or 5 years after the Grange was organized the price of fertilizers was reduced nearly one-half by buying in carloads. The Grange also sold to some extent. Mr. Clohan thinks, however, that the greatest benefits derived from the organization are social and moral rather than financial. The isolation of farmers causes them to become selfish and careless about the appearance of their places. Having a visiting committee resulted in a general improvement; if the Grange committee was going to visit a man's farm he would want to put in about a week getting the briars cut out, fences straightened up, etc. Mr. Clohan also emphasizes the value of the discussions on agricultural methods. (600.)

Mr. HALE says the Grange is doing splendid work in some States where it is working as an educational organization. In Michigan, New York, California, Pennsylvania, Ohio, New Jersey, and all the New England States it is doing grand work for agriculture. Mr. Hale believes there should be organizations of farmers for educational purposes in every community. (391.)

Vermont.—Mr. SPEAR testifies that the Grange in Vermont is more of a social business organization than strictly educational. (405.)

Massachusetts.—Mr. STOCKWELL says the Grange is doing an excellent work in Massachusetts and working in perfect harmony with the board of agriculture. It has done a great deal to add to the intelligence and attractiveness of the farmer's home. The Grange is very largely taking the place of farmers' clubs in Massachusetts, but some of the clubs still remain. Institute speakers are supplied to them where possible. (895.)

New York.—Mr. NORRIS, master of the New York State Grange, says granges have been established in all but about 6 counties of that State. The Grange has organized fire relief associations throughout New York, which have saved the farmers thousands of dollars in safe and economical insurance. (320, 329.)

Mr. Norris says the Grange is not a political organization; partisan politics are never discussed in the order. Its ultimate objects are sociability, fraternity, and intelligence. (329.)

Illinois.—Mr. WILSON, master of the Illinois State Grange, says that organization has taken some action on the subject of public warehouses or elevators, but it has never crystallized into any definite legislation; the organization has never been strong enough. The Grange in Illinois is in a flourishing condition, however, and gradually increasing in numbers. Though not itself in business, the State Grange has made arrangements whereby the farmers can purchase supplies at very satisfactory prices. (250, 251, 253, 254.)

2. National Farmers' Alliance and Industrial Union.—Mr. HANLEY says the National Farmers' Alliance and Industrial Union of America represents a membership of something over 3,500,000 practical farmers and planters in the United States, composed of all shades of political and religious opinions. The main purpose of the union is to look after the interests of agriculture in a nonpartisan way, as manufacturers look after their interests. The farmers are organizing a trust to fight another trust and to resist its attempt to get products for less than the farmers are entitled to. (281, 282, 285.)

CCCLXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. Hanley testifies that the attitude of every member of Congress on matters of interest to agriculture is subjected to the closest scrutiny of the National Farmers' Alliance and Industrial Union. It is the policy of the society to use all its efforts to secure the nomination on all party tickets of farmers in agricultural communities, and thus assure the election of a representative of agriculture whichever party wins. The society will furnish its members with intelligence covering the acts of representatives in Congress and in State legislatures. (290, 291.)

3. Grain Growers' Association.—Mr. MORAN, president of the National Grain Growers' Association, says that association is composed entirely of wheat growers. The organization encourages the erection of farmers' cooperative grain warehouses, a number of which are already in existence. The association's convention at Fargo in the winter of 1898-99 is described as a "great gathering," the opera house being "filled from cellar to garret." There were lectures by very prominent men, including President James J. Hill, of the Great Northern Railroad. While the farmers formerly looked upon Mr. Hill as one of their worst enemies, from his meeting and talking to them at public meetings, they seem to have changed their views and now look upon him as a friend of the farmer. (709.)

4. Agricultural societies, etc.—Professor DAVENPORT says there is a strong tendency for farmers interested in the same line of agriculture to effect organizations. There are a great many live-stock breeders' associations, bee-keepers' associations, dairymen's associations, horticultural societies, etc., and still other organizations which aim to consider farming as a business. There is getting to be a strong desire on the part of farmers to study economic questions, which can not be considered at farmers' institutes, where political and religious subjects are barred. The National Pure Food Congress and other national gatherings of farmers aim to discuss broad questions involving the economic relations of agriculture to other industries. The discussions are devoid of the bitterness once exhibited, and the breadth of view is encouraging. (268, 269.)

Vermont.—Mr. SPEAR testifies that there is in Vermont a dairymen's association, a Merino sheep breeders' association, a horse breeders' association, a bee-keepers' association, and a maple sugar association, which obtain the best talent for instruction. There are also State and county fairs. (405.)

Ohio.—Mr. MILLER says there were movements made in scientific agriculture by a few prominent agriculturists of Ohio as early as 1832, but they had not unified their work so as to form a State organization until 1846, when the State Board of Agriculture was organized. (608.)

South Carolina.—In Mr. HAMMOND's neighborhood in South Carolina there is an agricultural society or farmers' club which has held monthly meetings, except for a month or two during the war, since 1843. Discussion lasts from 11 to 2. There are two or three men who speak every time, and no one else speaks. It is, however, a pleasant social gathering and profitable. (829.)

Georgia.—Mr. STEVENS says that for nearly 60 years there has been in Georgia a State agricultural society, an organization of the leading agriculturists of the State, also a horticultural society and a dairy association. The object sought is the improvement of agriculture, horticulture, and dairy methods. These societies, together with similar less known organizations, have been very beneficial to the State. (915.)

Louisiana.—Dr. STUBBS says the State agricultural society composed of the farmers and planters of Louisiana holds a week's session annually. The leading farmers and planters take part. (782, 783.)

Dr. Stubbs testifies that the Northern Louisiana Agricultural Society holds its monthly meetings on the grounds of the experiment station at Calhoun, where it has built a hall. People from the adjoining parishes attend the meetings not only for the agricultural benefits, but also to see each other and find out what is going on. Once a year the society holds an agricultural camp meeting on the station grounds, lasting 3 days. There is no charge, and from 3,000 to 7,000 people are on the grounds during the whole time. They pitch their tents and camp out. The adjoining parishes, through their police juries (corresponding to county commissioners) contribute from \$25 to \$100 a year to a premium farm fund. The mornings are devoted to discussion of agricultural subjects by educators or farmers, the afternoons to the examination of stock and other exhibits, and the nights to question boxes. Any planter may ask a question, and it is answered by anyone who can answer it. (780, 781.)

Dr. Stubbs says enormous exhibits are always made at these meetings, and from \$300 to \$500 a year, contributed by the adjoining parishes, is distributed in premiums. Public-spirited citizens add to the amounts given by the police juries, and the merchants give certain premiums. The interest is growing. There are usually from 100 to 200 horses and mules on exhibition, mostly home raised, besides cows, hogs, sheep, and farm products. There is no trotting and no betting. (781.)

Mr. AGER, master of the Maryland State Grange, says that the Grange was organized for social, educational, and financial benefits. The educational feature was considered especially important, and he thinks the greatest benefit of the order is educational. The members must be engaged in agriculture or in occupations which do not conflict with it; clergymen and school teachers are admitted. The State of New Hampshire has 21,200 members in more than 200 granges, but the order is not generally prosperous in the South. There was at one time a strong organization in Maryland, but it has been materially reduced. Many were disappointed because it did not assume political features, and many others expected it would put money in their pockets without any effort on their parts. At each meeting questions are selected for discussion at the next meeting, and papers are read on those questions. Any question of interest to agriculturists is acceptable, but partisan politics and sectarian religion are excluded. Professors from the Department of Agriculture and from the Maryland Agricultural College are often invited to the county meetings, which are held quarterly. The order has National, State, county, and local organizations. National and State convocations are held annually. Mr. Alger thinks the grange has been beneficial in making better farmers and better citizens, and that the social feature is of much value. Members make many acquaintances, and there is a beneficial fraternal feeling existing in the order. The Grange holds to the principle of doing business for cash, maintaining that it is better to hire money and pay interest than to go in debt. (113, 114.)

Mr. CLOHAN says the Patrons of Husbandry have been in existence at least 25 or 30 years in West Virginia, and the farmers connected with the organization have improved their methods of farming and of buying and selling. Within 4 or 5 years after the Grange was organized the price of fertilizers was reduced nearly one-half by buying in carloads. The Grange also sold to some extent. Mr. Clohan thinks, however, that the greatest benefits derived from the organization are social and moral rather than financial. The isolation of farmers causes them to become selfish and careless about the appearance of their places. Having a visiting committee resulted in a general improvement; if the Grange committee was going to visit a man's farm he would want to put in about a week getting the briars cut out, fences straightened up, etc. Mr. Clohan also emphasizes the value of the discussions on agricultural methods. (600.)

Mr. HALE says the Grange is doing splendid work in some States where it is working as an educational organization. In Michigan, New York, California, Pennsylvania, Ohio, New Jersey, and all the New England States it is doing grand work for agriculture. Mr. Hale believes there should be organizations of farmers for educational purposes in every community. (391.)

Vermont.—Mr. SPEAR testifies that the Grange in Vermont is more of a social business organization than strictly educational. (405.)

Massachusetts.—Mr. STOCKWELL says the Grange is doing an excellent work in Massachusetts and working in perfect harmony with the board of agriculture. It has done a great deal to add to the intelligence and attractiveness of the farmer's home. The Grange is very largely taking the place of farmers' clubs in Massachusetts, but some of the clubs still remain. Institute speakers are supplied to them where possible. (895.)

New York.—Mr. NORRIS, master of the New York State Grange, says granges have been established in all but about 6 counties of that State. The Grange has organized fire relief associations throughout New York, which have saved the farmers thousands of dollars in safe and economical insurance. (320, 329.)

Mr. Norris says the Grange is not a political organization; partisan politics are never discussed in the order. Its ultimate objects are sociability, fraternity, and intelligence. (329.)

Illinois.—Mr. WILSON, master of the Illinois State Grange, says that organization has taken some action on the subject of public warehouses or elevators, but it has never crystallized into any definite legislation; the organization has never been strong enough. The Grange in Illinois is in a flourishing condition, however, and gradually increasing in numbers. Though not itself in business, the State Grange has made arrangements whereby the farmers can purchase supplies at very satisfactory prices. (250, 251, 253, 254.)

2. National Farmers' Alliance and Industrial Union.—Mr. HANLEY says the National Farmers' Alliance and Industrial Union of America represents a membership of something over 3,500,000 practical farmers and planters in the United States, composed of all shades of political and religious opinions. The main purpose of the union is to look after the interests of agriculture in a nonpartisan way, as manufacturers look after their interests. The farmers are organizing a trust to fight another trust and to resist its attempt to get products for less than the farmers are entitled to. (281, 282, 285.)

CCLXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

break away from their own store and buy where they can buy cheapest. Mr. George doubts the possibility of organizing farmers thoroughly for commercial ends. He has worked at it for several years, but there are so many interferences that failure seems inevitable. The leaders become ambitious and want offices, or some outside influence makes use of the Grange or the Alliance for its own benefit. (222.)

5. Proposed legislation in aid of cooperation.—Mr. HOLMES is of the opinion that cooperation among farmers would be strengthened by legislation promoting honesty and efficiency of administration. He suggests that incorporated cooperative companies should be subjected to the supervision of a State officer or commission corresponding to that to which banks and insurance companies are subjected, the supervision to consist of examination of accounts and publicity of the business. He believes this would protect many cooperators. Mr. Holmes would prefer that Congress should legislate for the cooperative corporations engaged in interstate commerce, if possible. (160, 161.)

XVIII. GOVERNMENTAL ACTION IN BEHALF OF AGRICULTURE.

A. United States Department of Agriculture.—1. **A national department of applied science.**—Dr. TRUE compares the United States Department of Agriculture to a great agricultural experiment station, both working along the higher lines of scientific research to more practical lines and giving out a large amount of information. (139.)

Professor DAVENPORT quotes Secretary Wilson to the effect that the United States Government interests itself in agriculture in three ways: (1) In collecting information about agriculture as a commercial enterprise; (2) in investigating the principles of agriculture, through the Department of Agriculture and the experiment stations; (3) through the establishment of agricultural colleges in each State. (259.)

Requests for information.—Mr. WHITNEY says the Department of Agriculture is constantly in receipt of requests for information as to where certain settlements of people could be made to grow certain crops, and very frequently the utmost ignorance is shown as to localities and conditions. (860.)

Dr. WILEY says the men who are putting their money into the beet-sugar industry come to the Department of Agriculture to ask where to locate their factories, because the Department has collected the data and studied the subject, not from a monetary, but from a purely scientific point of view. A large factory built in Colorado in 1900 was located by the Department of Agriculture; a great many localities in the State wanted the factory and were bidding for it, but the investors wanted to put the factory in the region that would produce the most business. Some capitalists who desired to locate a factory at Fredericksburg, Va., applied to the Secretary of Agriculture for information, and he advised them not to do so, though very good beets could be grown there, because beets grown 300 miles farther north had a sugar content 4 per cent greater and would make 80 pounds more sugar to the ton at the same expense; their competitors farther north could therefore undersell them in any market. (648.)

Distribution of bulletins.—Dr. HOWARD says that owing to recent Congressional legislation there is only one class of bulletins of the Department of Agriculture which can be freely distributed to all applicants, namely, the Farmers' Bulletins. For the large bulletins the mailing list is restricted, but they can be purchased from the Superintendent of Documents for 5 or 10 cents apiece. The Division of Entomology issues circulars giving concise directions about specific insects. (762.)

Scientific aids in the Bureau of Soils.—Mr. WHITNEY says several college men have agreed to go into the Department of Agriculture at low salaries (\$40 a month) and put themselves under the direction of the tobacco expert employed by the Bureau of Soils. They will go into the tobacco sheds and learn how to handle tobacco, and then will have some training in the laboratories in the principles underlying the manipulation of tobacco. Mr. Whitney predicts that these young men will go out from the Department at salaries of from \$3,000 to \$5,000, as other men have who have been trained in the Department. Men are leaving positions in which they were getting \$1,000 or \$1,200 and coming to the Department for \$40 a month and the experience they can get there. Young men readily come to the Department at such low salaries because they acquire an intimate knowledge of farming operations, of soils, of the production and management of tobacco, etc. Some of the young men from the Department have had offers to go out West and protect lands from alkali at \$2,500 or \$3,000. (867, 868.)

2. Bureau of Animal Industry. (See also *Diseases of animals*, XI B, p. CCLXXI; *Exclusion of American cattle from European countries*, XV B 3, p. CCLXVI.)—Dr. SALMON,

Chief of the Bureau of Animal Industry of the United States Department of Agriculture, classifies the work of that Bureau under eight heads, as follows:

- A. Control of contagious diseases of animals in the United States.
- B. To prevent importation of contagion.
- C. To prevent exportation of contagion.
- D. Meat inspection.
- E. Investigation of diseases and remedies.
- F. Cooperation to prevent disease.
- G. To aid exports.
- H. Collection of information.

Control of contagious diseases of animals in the United States.—Dr. SALMON says the disease particularly in view when the Bureau of Animal Industry was established was contagious pleuro-pneumonia of cattle, which was causing much anxiety among stock raisers and had interfered with exports of live cattle. This disease was completely stamped out by cooperation between the Bureau of Animal Industry and the authorities of the interested States.

The disease second in importance was Texas fever, to prevent the spread of which a quarantine line was established. (See map facing p. 742.) The portion of the country south of this line is permanently infected with Texas fever, and while the cattle in that area do not suffer greatly from the disease, they carry the contagion with them when they are taken to other parts of the country, and so produce fatal outbreaks. The quarantine does not prevent the shipment of cattle by rail for slaughter, provided proper precautions are taken in unloading; and cattle to be sold for grazing are allowed to be shipped from the infected district during November and December without restriction. The result of the quarantine and inspection has been to prevent Texas fever almost entirely in the territory north of the quarantine line, and also to prevent its development among cattle en route to Europe.

Sheep scab, though easily cured, has not been easily understood by sheep owners, and has spread until it has become one of the greatest obstacles to the prosperity of the sheep industry. Inspectors have recently been stationed in the Western States and Territories to prevent the shipment of diseased animals and to supervise the dipping of diseased sheep. Inspection for this disease is also maintained in the principal stock yards.

During the quarantine season of 1899 the employees of the Bureau inspected and supervised the movement of 1,058,484 cattle, and supervised the disinfection of 39,663 cars in which infected cattle had been carried; 1,801,379 sheep were examined for sheep scab, and 626,838 were dipped under the supervision of the inspectors. (742.)

Efforts to prevent the importation of contagious diseases.—Dr. SALMON says that animal quarantine stations have been established at Boston, New York, and Baltimore, where cattle from countries where pleuro-pneumonia has existed are held in quarantine for 90 days; other ruminant animals and swine are detained 15 days. Inspection and quarantine stations have also been established along the Mexican and Canadian borders. Tuberculin tests are also required in order to guard against the importation of animals infected with tuberculosis. Inspectors have recently been sent to Great Britain and to Canada to make tuberculin tests, so that diseased animals may be rejected before shipment. (742.)

Efforts to prevent exportation of contagion.—Dr. SALMON says that horses, cattle, and sheep are inspected before shipment in order to prevent the exportation of contagion. The animals are marked with tags, and health certificates are issued for cattle and horses; it has been impossible to issue certificates for sheep, on account of the existence of sheep scab and the general infection of stock yards and cars. During the fiscal year ending June 30, 1900, 305,182 export cattle, 73,426 sheep, and 37,080 horses were thus inspected. (743.)

Meat inspection.—Dr. SALMON says meat inspection has been established at the principal packing houses to guard against the interstate and foreign shipment of diseased meat. The inspection is made before the animals are slaughtered and again when the carcasses are being dressed. The sound and wholesome meat is marked for identification and certified to in accordance with the law. During the fiscal year 1899-1900 34,737,613 carcasses were inspected.

A microscopic inspection of pork for trichinæ is also maintained, but it is applied only to pork for export to countries which require such inspection. The greater part of the pork products goes to Germany and France. Only 55,809,626 pounds of microscopically inspected pork were exported during the fiscal year 1899-1900, though in some previous years as much as 120,000,000 pounds have been exported. (743.)

The Bureau of Animal Industry makes an agreement with abattoir managers that they will dispose of condemned meat according to the regulations of the Bureau. There is no law authorizing this arrangement, but the Bureau has not been able to

cover the entire country with its inspection, and will not put an inspector into an abattoir unless this is agreed to. When meat once gets on the market it is impossible to know whether it stops in the State where the slaughter was done or is shipped out. A Federal inspector once condemned a tuberculous steer which the Illinois inspector passed. The State commission demanded that the carcass should be turned over to it to be used locally. On investigation it was found that it had been sold to a large canning establishment in Chicago, and it was impossible to say whether it was to be used in Illinois. (745.)

The Bureau inspects all the large abattoirs which purport to do interstate business, but has not been able to cover all the smaller places that do interstate business. The 34,000,000 animals inspected during the year 1899-1900 included about 5,000,000 cattle, 6,000,000 sheep, and over 23,000,000 hogs, by far the greater part of the animals slaughtered for meat. Dr. Salmon does not see his way clear to include in the inspection the large number of small places where 50 to 100 hogs and 10 to 15 cows are killed daily; the Bureau has not been able thus far to get enough inspectors for the purpose, although the appropriations have been as large as could be used to advantage. Dr. Salmon estimates the entire slaughtering of bees at 8,000,000 or 7,000,000 a year. (750.)

Investigation of contagious diseases and their remedies.—Dr. SALMON says that investigations have been conducted with reference to Texas fever, hog cholera, sheep scab, tuberculosis, rabies, and various other diseases.

Texas fever.—All of the mysteries regarding Texas fever have been cleared up, and it is now possible to control it very effectually. The species of tick which causes the disease is being eradicated in many sections, and it is possible to inoculate the cattle needed in the Texas fever district for breeding purposes before they are shipped from the Northern States so that they will resist the fever when exposed to it.

Hog cholera.—The prevention of hog cholera is a problem on which the experts of the Bureau are still working.

Sheep scab.—In the control of sheep scab it very early became necessary to use dips, which will cure the disease without injurious effects, and two standard dips have been adopted.

Tuberculosis.—Investigations have been made to determine the prevalence of tuberculosis, the effect of tuberculin when used for its diagnosis, and the infectiousness of dairy products.

Rabies.—Investigation shows that rabies has become very common in the United States. Not only does it affect dogs, but a large number of horses, cattle, and swine are bitten and die of it. Many persons are also bitten, and a considerable number of them contract the disease. (743, 744.)

Cooperation with State authorities and individual stock owners.—Dr. SALMON says the Bureau supplies State authorities with tuberculin to be used in testing animals for tuberculosis. The tuberculin is manufactured in the laboratory of the Bureau, and is supplied free of expense for official use.

Mallein, for detecting glanders in horses, is supplied in the same manner, both to State authorities and to the War Department. The Bureau has also been making vaccine for blackleg in cattle, which is supplied directly to cattle owners.

Where the Texas fever quarantine line crosses a State or Territory, as in Virginia, North Carolina, Georgia, Tennessee, Oklahoma, Texas, and California, the line is maintained by cooperation between the State authorities and the Federal Bureau. The Federal authorities alone could only make a quarantine line corresponding with the boundaries of States. (744.)

Dr. Salmon adds that Texas fever is almost entirely prevented by this cooperation. The quarantine line is made in the first instance on State lines; then in the case of States which are partially free from infection and which will cooperate with the Federal Bureau, it is put across the territory of the State. That is a great inducement to cooperate. (750.)

Dr. Salmon says the Federal Government has done nothing toward stamping out any disease except pleuropneumonia and sheep scab. It has never gone into the States and condemned animals except in the pleuropneumonia work. That was a great emergency, and in most cases the States made the Federal inspectors State inspectors also, the expenses, however, being borne by the Federal Government. (749.)

Promotion of exports of animals and animal products.—Dr. SALMON says that besides the trichine inspection and the inspection of live animals and meat for export, the Bureau maintains an inspection and control of cattle fittings on steamers carrying animals to Europe. The strength, space, ventilation, etc., and the number of attendants are prescribed. These regulations have reduced the losses in transit tremendously. When the regulations went into effect the insurance upon export cattle was about 8 per cent of their value; it is now considerably less than 1 per cent.

Experimental shipments of butter, cheese, and eggs have also been made, and much has been done to create a demand for these American products, especially in Great Britain. (744.)

Collection of information.—Dr. SALMON says information is collected and diffused in regard to (1) the nature and treatment of prevailing diseases, (2) the characteristics of various animals and the methods of breeding and feeding them, (3) the dairy industry, and (4) the animal industry generally. (745.)

Personnel—Appointment, qualifications, and tenure of office.—Dr. SALMON says all the inspectors, assistant inspectors, microscopists, stock examiners, and taggers are appointed under civil-service rules, and are not changed for political reasons. The microscopists do not have steady work, their work varying with the export trade. The majority of the inspectors and assistant inspectors are quite young, because they are appointed at \$1,200 a year, and also because a young man fresh from college can pass an examination better than one who has been in practice for a time. Dr. Salmon says the establishment of his Bureau has been of advantage to the science of veterinary surgery by the investigation of a number of diseases that were not understood before, and has also been of advantage to the profession by furnishing employment for a number of men. All the inspectors and assistant inspectors are veterinarians. This demand for veterinarians has led in turn to an effort to supply the demand by the establishment of veterinary departments in a good many colleges. (750, 753.)

Attempted bribery of inspectors.—Dr. SALMON says that in one Western abattoir attempts were made to bribe three inspectors of the Bureau. The inspectors had been changed in order to get additional evidence. Action was then brought against the manager of the abattoir, but the judge decided the inspection law unconstitutional on the ground that the meat did not become a subject of interstate commerce until actually in shipment, and refused to apply any penalty. As this was a criminal case it could not be appealed. Dr. Salmon thinks the inspectors are honest and report any improper advances on the part of the abattoir managers, but after a man gets acquainted with the abattoir authorities it is human nature to be lenient with them, and this can only be counteracted by changing the inspectors. (752.)

Inspectors in Europe.—This Bureau has 3 inspectors in Great Britain, 2 for cattle and sheep and 1 who inspects the cattle coming from Great Britain. Our meat exporters are required to pay for the meat inspection in Germany and France. (751.)

International cooperation.—Dr. SALMON says that his Bureau has more or less correspondence with scientific investigators abroad, and hears of everything they do. There is more or less cooperation by exchange of material for investigation, but no cooperation in executive work. (751.)

3. Bureau of Forestry.—Mr. WHITNEY says the Division [now Bureau] of Forestry concerns itself with the problems of reforestation, protection against forest fires, and more rational methods of cutting timber. (878.)

4. Division of Entomology.—Dr. HOWARD says that when he first came to Washington the only appropriation for entomological work was for the salary of the entomologist and one assistant. Now there is an annual appropriation of about \$10,000 for statutory salaries, besides a lump fund of \$22,500, about three-fourths of which is expended in salaries of investigators who may be used in any investigation. The Division has recently investigated a good many special topics, e. g. insects attacking garden crops and citrus crops, beneficial insects from abroad, etc. The work could be done more expeditiously with larger appropriations. Dr. Howard feels sure that a great deal more money could be spent to the advantage of agricultural classes. He cites the increase of the appropriations, however, as showing that the appreciation of the importance of his work is growing. (763.)

A certain amount of work is done in cooperation with State authorities. Dr. A. D. Hopkins, of West Virginia, who has paid special attention to insects injurious to forest trees, has been employed by the Division of Entomology to study the damage done by insects to the forests of Washington, Oregon, Idaho, and Maine. The experience which he gains in this way is of value both to the State and to the General Government. Other State officials have been employed in the same way. There is also an association of all the economic entomologists; each man studies conditions in his own locality and the association brings the information together. (761, 762.)

5. Work of other divisions and bureaus in relation to insects.—Dr. HOWARD says it is almost impossible to get a pure *paris green*, but the Division of Chemistry is analyzing a large number of chemical insecticides. The Division of Vegetable Physiology and Pathology studies the diseases of plants, some of which are spread by insects. The wilt of the melon leaf, for instance, a bacterial disease, is carried by insects. There are many insects which are injurious to animals—the horse bot, the ox warble or grub, the sheep bot, etc.—and they come within the scope of the Bureau of Animal Industry. (762.)

6. Investigations of food and foodstuffs.—Dr. WILEY, Chief Chemist of the Department of Agriculture, says the making of macaroni is a large industry in San Francisco, because of the large Italian and other foreign population, and the Pacific wheat until recently made an excellent article; but complaints were made by the millers that the wheat would not make macaroni as it did a few years ago. The Department of Agriculture, on investigation, found that the content of gluten had fallen so low that the wheat was no longer suitable for making macaroni. Dr. Wiley mentions this as an instance of an investigation which a wheat grower or miller would hardly be willing to undertake, while the Agricultural Department, in the interest of agriculture as a whole, can do a good work by pointing out the causes which produce the depreciation, and if possible suggesting remedies. (643.)

Mr. A. J. WEDDERBURN, corresponding secretary of the National Pure Food and Drug Congress, has made several reports on food adulteration as special agent of the Department of Agriculture. One of these was on the adulteration of butter and butter nostrums, published with considerable addition as *Farmers' Bulletin No. 12*. Another was a report on the adulteration of flour, which was published by order of the Ways and Means Committee of Congress, and was followed by legislation in the early part of the Fifty-fifth Congress compelling the branding and taxing of adulterated flour. (619, 620, 633.)

Mr. Wedderburn also made reports Nos. 25, 32, 40, and 41 of the Division of Chemistry. He refers to the various parts of *Bulletin No. 13* as the most extensive and best literature on the subject of food adulteration in the world. (619, 620, 633.)

7. Sugar-beet seed station.—By authority of Congress a station was established in Nebraska under the control of the Department of Agriculture, with Dr. WILEY as director, to see what influence the soil and climate of the United States would have upon the production of a high-grade sugar beet. The station was continued only 3 years, but it proved that the seeds grown in this country, when planted side by side with imported seeds of the same character, produced beets averaging 20 pounds of sugar more to the ton than those grown from European seed, a perfect demonstration that we should produce our beet seeds here, even if by a costly process. No further attempts have been made by the Government to grow high-grade seed, nor have any private individuals engaged in the business. The Secretary of Agriculture who took office in 1893 did not believe in any kind of paternalism, and he called the growth of seed "paternalism gone to seed," so he abolished the station and sold all the appliances. No further attempts have been made by the Government to grow high-grade seed, but some of the experiment stations are devoting their attention to the matter. (See *Bulletins 30, 33, and 36, Division of Chemistry.*) (642, 644.)

Dr. Wiley thinks it would be very advisable for the Government to continue the work of demonstrating how beet seeds can be produced, but not to produce them commercially. Dr. Wiley is opposed to the free seed distribution of the Government as bad in principle, but declares it the duty of the Government to do a work which no individual will do, because it is without any possibility of pecuniary gain. In the absence of private endowment for such purposes, it is the duty of the Government to promote the interest of agriculture in every line. The development of high-grade seeds in this country is necessary from a pecuniary point of view. We can not afford always to import our seeds; they are worth 10 cents a pound by the cargo, and at least 20 pounds should be planted to the acre. If we have 100,000 acres planted in beets we are sending at least \$200,000 out of the country each year for beet seed, and as the industry increases we must produce the seed at home. (643, 644.)

8. Office of Experiment Stations.—Dr. TRUE testifies that the Office of Experiment Stations is a sort of clearing house for agricultural education and experimentation; it receives the reports and bulletins of all the agricultural colleges and experiment stations in this country and many foreign countries, reviews them, and publishes as much of their contents as may be of general advantage in America. Personal visits have been made to every part of the United States and to many European countries, for the purpose of studying questions pertaining to agricultural education and experimentation. (138.)

Irrigation investigations.—Mr. MEAD gives a list of the publications of the Office of Experiment Stations on irrigation, published since his connection with the Department as expert in charge of irrigation investigations. (1049, 1050.)

9. Division of Statistics.—Mr. HYDE, Statistician of the Department of Agriculture, says that while the necessity of agricultural statistics is unquestionable, there are far greater difficulties encountered in their collection than in the case of any other great department of the world's business, such as mining or manufacturing; partly because of the character of the business, and partly because of its wide distribution and the minute subdivision of operations. These difficulties can not be overcome by indi-

DIGEST:—DEPARTMENT OF AGRICULTURE. CCCLXXIII

vidual effort. It was perhaps the greater facility with which a knowledge of the operations of other branches of business is obtained that gained for them their much earlier and more adequate recognition in legislation. The collection of agricultural statistics was for many years the work of an obscure section of one branch of a bureau in the Department of the Interior; but a statistical office early became a necessity to the farmers, and such a branch of the Department of Agriculture has been in continuous operation since 1863. Some of the most general and greatest benefits which have accrued to agriculture have been the result of knowledge obtained from this office. It tends to increase the rewards of industry by augmenting production through the analysis of comparative results by the maintenance of equilibrium between supply and demand, and by contributing to stability of value through reducing the risks of trading to a minimum.

The Division of Statistics issues monthly statements relating to the existing conditions throughout the country, based largely upon data obtained from voluntary correspondents. Besides about 2,750 principal county correspondents, each of whom has 3 assistants covering specified districts, and from 6 to 15 township correspondents in each county, there are 43 salaried State statistical agents, each of whom maintains an independent list of correspondents completely covering the State, and ranging from 20 to 700 in number. The returns are carefully tabulated and weighted according to the relative importance of each county represented before the summarized report is submitted to the Department. From States west of the Mississippi the reports of State agents are telegraphed in cipher.

No individual is allowed to serve upon any two of these groups of correspondents. The tabulated reports of the correspondents and State agents are brought together on the 8th of each month, providing the Statistician with 3 separate estimates, covering the same territory and the same crops, made by separate corps of correspondents, each reporting for a territory with which he is thoroughly familiar. These data, however, are supplemented by the reports of salaried special field agents who systematically traverse the producing portions of the country, procuring all possible data and carefully analyzing the situation, while reports concerning the final yield per acre are further obtained from a very large list of individual producers, each reporting for his own farm. The total number of correspondents of all classes in the crop-reporting service aggregates nearly 250,000.

In tabulation the figures are carefully weighted so that each county and State may have its proper influence in determining the totals, according to its crop importance. The census figures are used as a basis, acreage and production being carried from year to year by the percentage method. Correspondents are asked to report in percentages, comparing the acreage and production with that of the preceding year, and the condition of crops with a normal condition. The yield per acre and prices are reported quantitatively.

The cotton reports obtained in the manner above described are supplemented by returns on special schedules from a list of special cotton correspondents, embracing a very large number of persons intimately concerned in the industry, a complete list of cotton ginneries, and a list of planters, each reporting for his own plantation. This method of investigating cotton production, however, is employed only for making a preliminary statement, the final figures being derived from statistics of movement and consumption obtained from transportation companies, port officials, and mills. This final report can not be completed until after August 31, the close of the commercial cotton year.

Statements relating to live stock and the principal farm crops, except cotton, are made public on the 10th of each month; the cotton statements are issued on the 3d of each month during the growing season. The statements are sent out by telegraph, so that the information may be made available simultaneously throughout the country; and in order that the information may be placed within easy reach of the farmer at the earliest possible moment, printed cards are mailed to every postmaster in the United States within a few hours of the time when the statements are telegraphed, to be posted conspicuously for the information of the public. (840, 841.)

Mr. Hyde says the crop reports might be positively detrimental to the interests of farmers if possessed by only a few persons or restricted to commercial circulars. It is therefore the aim of the Division of Statistics to make the widest possible distribution of the information it receives as promptly and speedily as is consistent with accuracy. The monthly crop reports are mailed as promptly as possible to the State statistical agents and those who report to them; to the county correspondents and their assistants; to the township or district correspondents; to cotton planters; to 1,200 newspapers, mostly rural; and to other persons, mainly farmers. The reports relate at different seasons to the conditions of soil, weather, planting, growth, harvesting, yield, quality, transportation, markets, and prices. They are sent regularly and

CCCLXXIV THE INDUSTRIAL COMMISSION:—AGRICULTURE.

gratuitously to all persons who ask for them, and the demand for them leaves little doubt that considerable value is set upon them. (842.)

Mr. Hyde says that in the promotion of relations of mutual benefit between producers and consumers the Division of Statistics has benefited agriculture to an incalculable extent, and has incidentally benefited all legitimate occupations and all consumers. He predicts that when certain improvements in the crop-reporting service shall have been made, there will be no division of any Government department, and certainly no independent organization, that will be promoting so greatly and so generally the agricultural interests of the country. The benefits conferred upon agriculture by statistics have no more attained their full limits than agriculture has attained its full development. Through the gradual utilization of whatever knowledge of physical conditions and of human needs may be available and susceptible of numerical expression, and the exposition of its relation to agriculture, the statistician of the future will be able to promote the agricultural interests of the country in directions now hardly dreamed of. (842.)

Mr. BUDGE, of North Dakota, is of the opinion that the monthly crop reports have a tendency to apply the rule of supply and demand, and to that extent at least counteract the effect of gambling in grain. He considers the crop reports a good thing. (857.)

Criticisms of the crop reports.—Mr. HAMMOND thinks that speculation in cotton is stimulated by the Government crop reports, and that the stimulation is largely unnecessary and due to the unreliable character of the reports. The Government statements, he says, are mere guesses. They might be made much more reliable. He would have the Department of Agriculture prepare a township map of the cotton belt, showing the amount of the crop in each, according to the most accurate enumeration available. Then he would have paid inspectors make some 8 tours of inspection during the year, visiting certain townships and portions of townships, and by personal inspection obtain actual figures upon which the Department might base estimates of the growing crop. Such figures would be the average number of plants in a given length of row, their average height, the count of bolls under definite regulation, etc.

But after the picking season begins, the gin-house returns would furnish the best basis for a forecast of the crop. Ginneries, like other manufacturing establishments, are being consolidated. The public ginney is superseding the old plantation gin house. The public ginner has no interest in withholding information as to the number of bales turned out, and it is a part of his business to know what the small gin houses in his locality, competing with him, are doing. Unbiased reports could be obtained from him. They can not be obtained from the cotton growers who correspond with the Department. All the cotton goes through the ginneries within a short time after it is gathered. Ginned cotton may be stored for months and years on the plantation and in warehouses, but unginned cotton is not. By December 31 95 per cent of the cotton is ginned; and if the Department would get returns from the gin houses, the size of the crop might be accurately known. (831, 836-838.)

Mr. DYK believes that there is a certain tendency for the bulletins of the Department of Agriculture to overestimate the probable crops, thus tending to depress prices. The time of greatest injury to the crops is that of maturity, so that previous estimates are apt to be unduly exaggerated. (97, 98.)

Mr. MORAN, president of the Grain Growers' Cooperative Association, desires the abolition of the forecast crop reports of the Department of Agriculture, on the ground that it is one of the most disastrous elements in destroying the value of farm products. These reports, he says, can not be accurate until the thrashing machine has done its work. (720.)

10. Section of Foreign Markets.—Mr. HITCHCOCK testifies that the section of foreign markets of the Department of Agriculture depends as far as possible upon the official reports issued by various foreign governments. It also has had the cooperation of the United States consular service and some assistance from special agents employed by the Department of Agriculture to study agricultural conditions in foreign countries. For information concerning our own export trade the office is very largely dependent upon the reports of customs officials published by the Treasury Department. (666.)

11. Introduction of American products abroad.—Mr. SNOW testifies that Secretary Rusk secured an appropriation for introducing American products abroad, but the work was stopped 2 years after its inception, so there has never been a fair opportunity to judge what might have resulted. The agent selected by Mr. Rusk went to Denmark and solicited grocers to handle some American products, and with the United States minister gave a dinner of corn products. Denmark did not then import a pound of American corn products, but from that time there has been an

increasing trade in these products with Denmark, amounting (1899) to 20,000 or 25,000 barrels of corn meal a year, and still increasing very rapidly. (239.) (See also *Increased exportation of grain impracticable and undesirable*, XV D 3, p. CCCXLIX.)

18. Suggested extensions of the Department's work. (See also *Proposed agencies for developing foreign trade*, XV E, p. CCCXLIX.)—MR. MORAN, president of the National Grain Growers' Cooperative Association, says his association desires an official inquiry into the cost of raising grain, cotton, and meat, to be undertaken by the National Department of Agriculture, in order to furnish accurate data as a basis for remedial legislation. (720.)

The association also approves increasing the annual appropriation for the Department of Agriculture to at least \$10,000,000, to enable it to keep pace with the importance of the greatest industry of the country. (720.)

B. State departments of agriculture.—1. New York.—MR. FLANDERS, Assistant Commissioner of Agriculture of New York, says that the New York State Department of Agriculture is an outgrowth of the Dairy Commission, which was created by an act of 1884 to stop the sale of adulterated milk and the fraudulent sale of oleomargarine as butter. An educational branch for the purpose of giving instruction to farmers in making uniform, first-class products was afterwards added to it. In 1893 more work was confided to it and the name was changed to Department of Agriculture. The educational work consists of imparting knowledge to the agriculturists of the State through a bureau known as the Bureau of Farmers' Institutes. The department now stops the fraudulent sale of oleomargarine as and for butter, filled cheese, cheese falsely branded as to quality, stops the sale of impure and adulterated milk, the sale of calves under 4 weeks of age, the sale of sugar made in imitation of maple sugar, the sale of vinegar containing less than 4½ per cent acetic acid, the sale of adulterated linseed oils, and the sale of condensed milk containing less than 25 per cent of butter fat. It is also charged with the enforcement of the law for the suppression or prevention of contagious and infectious diseases of domestic animals and with the suppression or extermination of infectious or contagious diseases of fruit trees. The department also distributes the State bounty for the production of beet sugar and the money appropriated by the legislature for agricultural fairs. (997.)

Mr. Flanders says that New York does not gather any statistics of agricultural products except those relating to butter and cheese manufacture. (998.)

2. Pennsylvania.—MR. HAMILTON, Secretary of Agriculture of Pennsylvania, says the department of agriculture of that State is organized very much as the National Department of Agriculture is. The secretary is appointed by the governor for a term of 4 years. There is a deputy secretary, also appointed by the governor, who is the director of farmers' institutes; a dairy and food commissioner, who has charge of the enforcement of the pure-food laws and does what he can to promote the dairy interests; a forestry commissioner, who has charge of the whole question of forestry; an economic zoologist, who looks after the diseases and insects affecting crops, investigating their habits and making suggestions for the suppression of their ravages; and a veterinarian, who has charge of the suppression and prevention of the diseases of domestic animals, and is a member of the State Live-stock Sanitary Board, which has very large powers in providing for the inspection and quarantining of diseased animals. These are also clerks and other subordinate officers. The secretary has a supervisory control of all the division officers, and is directly in charge of the inspection of commercial fertilizers and the enforcement of the law regulating their sale; he sees that samples are collected and analyzed and the results published. He also has a fund for making special investigations into matters of agricultural interest. The department has 4 correspondents in each county, who report on the prices of farm animals, crop statistics, and farm wages. (347, 349.)

3. Ohio.—MR. MILLER, secretary of the Ohio State Board of Agriculture, says there are no two State departments of agriculture similarly organized. Ohio has perhaps the most complete department of agriculture in the United States, except that of Pennsylvania. The laws of Ohio provide for county and district agricultural societies, which are entitled to send one delegate each to the annual meeting of the State Board of Agriculture at Columbus, in January. These delegates, together with 10 members selected at the previous meeting, who constitute the Board of Agriculture during the interval between the meetings, constitute the Board of Agriculture for the day on which the meeting is held. The president, vice-president, and treasurer are elected from the members of the board, and a secretary and assistant secretary, who may or may not be members of the board, are also chosen. (605.)

Mr. Miller says the law of Ohio requires the State Board of Agriculture to hold an annual State fair or exposition, and to conduct farmers' institutes throughout the State. The statutes also provide that the secretary of the board shall collect and publish agricultural and stock statistics and be the inspector of commercial fertilizers sold and used in the State. (605.)

Crop statistics.—Mr. MILLER says that Ohio has a very complete system of gathering statistics as to grain and stock conditions. There is a very great demand for the monthly reports, all the dealers considering them very valuable and trying to get them at the earliest moment. At times prices are affected by these reports. Mr. Miller thinks they tend to settle prices back to their normal conditions. (615, 616.)

Local fairs.—Mr. MILLER testifies that each local society organized under the laws of Ohio and operating under the rules of the State board draws a per capita allowance from the county funds, and is obliged to file with a board a statement under oath that all its rules have been complied with, and to make a full exhibit of its transactions. The State board does not allow any local society to permit the sale of intoxicants, or immoral exhibitions of any kind, at its fairs. The horse department is supposed to encourage the breeding of improved stock, and as speed is one of the requisites of a driving animal, they show the speed as well as the style and action of the animals; but no pool selling or gambling is allowed. There are also, however, what are called county agricultural societies which are distinct from those organized under the law and receive no allowance from the counties, and over which the State board has no control; these allow pool selling. (607.)

4. *Alabama.*—Mr. POOLE testifies that the Department of Agriculture in Alabama is supported from a tag tax on fertilizers which passes through the hands of the commissioner, and is covered into the treasury. An expense fund of \$500 a month is allowed the commissioner for holding farmers' institutes, for the purchase of seeds, etc. (919, 920.)

5. *Louisiana.*—Dr. STUBBS says the Louisiana State Board of Agriculture and Immigration consists of 1 farmer or planter from each Congressional district, together with certain ex officio State officials, including Dr. Stubbs, the Governor, the president of the agricultural college, the Commissioner of Agriculture, the director of the experiment station, and the vice-president of the board of supervisors of the agricultural and mechanical college. The board has an office in Baton Rouge, from which a large amount of agricultural literature is issued. (782.)

6. *Cooperation between national and State departments.*—Mr. MILLER says the laws have not been framed so as to bring about any considerable cooperation between the national and State departments of agriculture. (607.)

C. Various matters connected with government.—1. *Political representation of farmers.*—*In Congress.*—Mr. HANLEY gives statistics showing that of each 1,000 men in the Union Army in the civil war 487 were from agricultural pursuits. In contrast with this showing he quotes President Clayton of the Farmers' Congress as saying that the farming element of the country had only 35 members out of 444 members in the national House of Representatives and only 1 member in the Senate; that the chairman of the Senate agricultural committee and 10 of the 18 members of the House agricultural committee, including the chairman, were lawyers, and that the only chairmanship held by a farmer was that of the Committee on Ventilation and Acoustics. (290.)

Maryland.—Mr. AGER thinks that the farmers of Maryland are not as well represented in the legislature in proportion to the numbers and interests they represent as other classes. (114.)

West Virginia.—Mr. CLOHAN testifies that the farmers generally control the legislature of West Virginia, but always divide on political lines. (604.)

2. *Bills introduced in the New York legislature.*—Professor BAILEY, of Cornell University, says that 31 special bills in aid of agricultural interests were introduced in a recent New York legislature.

"A large number of these were regulatory and police measures. One made it obligatory upon State institutions to give preference to New York State products when buying supplies. One proposed to make it mandatory upon commission merchants to render to the consignor the names and addresses of purchasers, thereby affording the farmer a check on the middleman. One related to regulations concerning the sale and analysis of feeding stuffs. Eight had to do with adulteration and regulation of articles of food and feeding. Two related to sugar beets. Four were concerned with establishing legal sizes of packages. Four protected the farmer from nuisances, as weeds and rabbits. One sought to check the spread of diseases of bees. One related to the control of commercial fertilizers. Two appropriated money for the furtherance of agricultural education. With the exception of the two bills to promote education, all the 31 proposed measures aimed only to protect the farmer and to give him a fair chance to work out his own salvation. They could not make him a better farmer nor relieve any fundamental difficulty." (1010.)

3. *Fence laws.*—*Ohio.*—Mr. MILLER says Ohio has a law prohibiting the roaming of domestic animals at large, and the farmers are not obliged to use fences. He does not think they will use as much wire fencing as they would if prices were lower, but does not think farmers in Ohio will ever dispense with fences, having been educated from generation to generation to fence their farms. In some localities, however, it is a growing practice to discontinue the building of fences. (615.)

West Virginia.—Mr. Clohan suggests that if the fence laws of West Virginia could be dispensed with, it would do away with the wire trust, as far as barbed wire is concerned; but there is no law in the State governing the animals running at large, and the farmers have to depend upon their fences. (602.)

South Carolina.—Mr. HAMMOND says that the South Carolina farmers succeeded, after many years of effort, in passing a law requiring the fencing in of stock, and the punishing of owners who allowed their stock to trespass on the unfenced lands of others. He regards the result as injurious. Less fencing is necessary, but the amount of stock has diminished, and, since it is no longer necessary to preserve the woodland as a source of fence material, the destruction of the woods has gone on the faster. The fences also acted as barriers to the washing of the hills, and their removal has increased the damage from freshets. Mr. Hammond says one can drive 100 miles in the country without finding a fence. Probably no other civilized country has so few fences as South Carolina. (828, 834.)

4. Regulation of railroads and elevators.—Mr. NORRIS says the railroads and elevator men in the Northwest have unduly taken advantage of the producers, but he thinks that legislation has improved matters somewhat, so that they now ask only about one-half where they used to take two-thirds. (331.)

South Dakota.—Mr. M. F. GREELEY testifies that the people of South Dakota have not much confidence in the railroad commissioners, but are about as distrustful of them as of the railroads; perhaps too much so. The railroad commissioners are elected by the people. Mr. Greeley thinks the railroad commission has tried hard in a good many instances to afford relief, but there are so many changes and complications in the law and so many deferred trials that it does not get very quick or good results. (940, 943.)

5. Salaries of public officers.—According to Mr. JONES, the National Grange believes that for the most part the salaries of local, State, and national officers are more than commensurate with those paid for similar service in private life. The decrease in the prices of commodities has meant practically a large increase in salaries. The burden of taxes is a serious one. It is recognized that owing to the insecurity of public positions salaries should be somewhat higher, but the extravagant style of living of many public officials has a demoralizing effect on the minds of the people. Enough should be paid to secure the best service, and full and faithful service should then be demanded. (33.)

D. Proposed remedial legislation.—(See also under separate heads throughout digest.)—**1. Various proposed reforms.**—Mr. PECK, of Georgia, feels hopeful that much good will come from the Industrial Commission, and says the farmers need help, if anything can be done to help them. Mr. Peck proposes the following remedial legislation: (1) A change in the banking system (apparently to enable national banks to loan money on real estate); (2) an export bounty on all agricultural products; (3) Government ownership of transportation and other public utilities, and, pending that, an amendment giving the Interstate Commerce Commission power to enforce decrees; (4) restriction of land ownership. (462, 463.)

Mr. CLOHAN, of West Virginia, thinks there is no chance to relieve the ills of the farmer by legislation except in the matter of taxation, and perhaps in the control of railroad rates and accommodations. (603, 604.)

2. Regulation of trusts and other corporations.—Mr. BRIGHAM, Assistant Secretary of Agriculture, believes that there should be some regulation of trusts and great corporations. Though many of them claim that the public does not suffer from their actions, there is danger that they will prove oppressive when they get thorough control of the business. The State grants corporations special privileges and has a right to require them to do a legitimate business. State legislation has so far not proved very successful. Federal legislation is desirable, but is probably not constitutional unless the business is in some sense interstate. (26, 27.)

Mr. JONES, master of the National Grange, believes that the liberty of the people, the values of their property and of their labor are put in jeopardy by the growing power of trusts, and that there is need of legislation to restrain them. (31.)

Mr. POWERS says that some corporations are organized by villains to swindle the public. Some trusts are organized in that way, and some are legitimate, as some corporations are, and have honest men back of them. He predicts that the next few years will witness the collapse both of trusts and of small corporations organized fraudulently for swindling purposes and not under public control, causing much greater loss than the exactions of combinations in constraint of trade. (191.)

Mr. Powers says the existing legislation concerning trusts, which is largely prohibitive, is in line with the legislation of England from 1300 to the beginning of this century against organizations in restraint of trade, which was largely the regulation

CCCLXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

of labor. All these attempts in England for 500 years were futile, and in so far as the organization of capital is profitable it will grow in spite of legislation. (192.)

Mr. Powers emphasizes the need of bringing all corporations under complete public control and making their affairs public. The cry against trusts hides the real issue and delays the effort to secure the regulation of corporations until they are so large that the difficulty of regulation is increased. Mr. Powers believes that a large amount of the talk against trusts is fostered by certain classes of men who are promoting them and are interested in making the people believe that there are profits on all the watered stock they issue in order that they may sell that stock. He believes that there are men even in public life interested in trusts who are advocating laws against trusts, and expect to make their money in selling their stock when the collapse comes. Mr. Powers says that most of the State and national laws relating to trusts have resulted in giving trusts other forms, and have assisted the movement for the organization of great capitalistic combinations instead of deterring it. Mr. Powers advocates the regulation of corporations by the States in which they do business, as insurance and banking companies are regulated, though the principle would doubtless have to be modified in the details for each line of industry. Any State has the power to require publicity and to bar any corporation from doing business if it fails to observe reasonable regulations, even if it was created elsewhere. Such regulations would render ineffectual the plan of incorporation in one State for the purpose of getting around the laws of some other State. (191, 192.)

Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, also believes that the legislation that is needed for trusts is the same that is needed for smaller corporations. He does not believe it would be possible or wise to banish the trusts, but believes that there should be legislation which would enable individuals to protect themselves against powerful combinations. The average individual now has no power to gain redress because of the expense of litigation. The State is bound to supply this protection, because it granted to the corporations the powers they possess. (374.)

Mr. STOCKWELL, secretary of the Massachusetts State Board of Agriculture, considers enormous aggregations of capital and the unequal division of wealth a menace to our institutions. He feels sure that immense revenue to the rich by oppression of the poor can not continue. Exorbitant prices curtail the laborer's power to buy, and thereby the mills are rendered idle and the product is unsold. The farmer is the loser.

Mr. Stockwell conceives trusts to be an evil as they are now. The increased cost above what is necessary in any line is unjust, and to that extent a tax. (896, 897.)

It seems to Mr. Stockwell that national legislation should declare that great combinations and giant monopolies are not infant industries to be protected. Mr. Stockwell admits that the protective tariff helps to a limited extent the independent tinplate plants, but says it also puts immense profits into the hands of the trust, by which it can at any time destroy or absorb the weak industries; or perhaps they are allowed to live for the influence they have in sustaining the tariff.

As further remedies for trusts Mr. Stockwell advocates taxation and severe laws against combinations endeavoring to control trade. (897.)

Mr. Stockwell predicts that the large oil company which is trying to compete with the Standard Oil Company will eventually be dissolved, or else work in perfect harmony with the latter, as the so-called competing sugar refining companies have with the American Sugar Refining Company. The results of the contest between the American Sugar Refining Company and the Spreckels interests, and of the coffee war between Havemeyer and the Arbuckles, are not encouraging symptoms, and the fate of the smaller producers in their contest with the Standard Oil Company is not likely to encourage small capital to enter contests with large combinations. (897.)

Mr. HALE, a fruit grower, of Georgia and Connecticut, thinks trusts are a hindrance to trade, but does not think they can create a permanent monopoly. He would not be surprised if they went to pieces of their own weight. The life of trade is the individual back of small concerns. Taking the personal element out takes the life and soul out of business. Mr. Hale would rather have his money in a good farm than in a trust. (399.)

Mr. Hale thinks the removal of the tariff in the case of monopolies, while doing some good, might harm others. He suggests uniform legislation requiring publicity of accounts. (399.)

Mr. DYE, secretary of the New Jersey State Board of Agriculture, says men have a perfect right to consolidate capital for carrying on great industries, but when they attempt to monopolize trade, drive others out of the business, and fix prices, they ought to be regulated. (98.)

Mr. NORRIS, master of the New York State Grange, says the position of the farmers of New York is that anything that tends to make a monopoly of a product should be discountenanced. (332.)

Mr. STEVENS, commissioner of agriculture of Georgia, says it will require great wisdom to determine what regulations should be established for trusts and other forms of monopoly. Combinations of this kind should be intelligently resisted and broken down. There have been no favorable results from existing antitrust laws; something more far-reaching will have to be enacted before favorable results can be obtained. (916.)

Mr. GEORGE, of Chicago, thinks there are two sides to the trust question. Organization of capital is necessary to carry on great enterprises, but unless guarded against the trusts are a menace. Where there is no limit on nature's supply of an article, as in the case of ice, the trust may not have a monopoly, but may prove a great economy. It throws men out of employment, but by thus economizing it may deliver ice for 25 cents instead of 40 or 50 cents a hundred pounds. (225.)

Mr. HOLMES, of the United States Department of Agriculture, defines a trust to be an association of individuals, partnerships, or corporations for the purpose of regulating, maintaining, or raising prices or rates, or for the purpose of regulating the management of the undertaking, in which purpose there is a considerable degree of success, but not necessarily that of a monopoly. A trust, he says, may include farmers, dairymen, and fruit growers, and as a matter of fact these men have been organizing trusts in all parts of the country. (157, 158.)

Whatever legislation is enacted with regard to trusts must necessarily apply to this farmers' movement, which has been beneficial in no unreasonable sense to a large fraction of American producers. These associations are an outgrowth of the economic necessities of the time. They try to do away so far as possible with the middleman, who is one of the leeches of American agriculture. Mr. Holmes objects to the suppression of these agricultural trusts, but has no objection to their regulation. He believes in the regulation of trusts and of corporations, and would like to see their business subjected to publicity. (157-160.)

Mr. GREELEY, secretary of the Board of Regents of Education of South Dakota, advocates giving the Federal Government absolute power over all combinations of capital for the regulation of prices of products and transportation. Such control, he says, would do much to eliminate the feeling from the farming classes that every man's hand is against them, and that they must be sustained by favorable legislation. (941.)

3. Rural mail delivery.—Mr. BRIGHAM believes that farmers all desire the establishment of free rural mail delivery. They need it more than the people of the smaller towns. One man could save a hundred families from going a considerable distance for their mail. (27.)

Mr. STOCKWELL, secretary of the Massachusetts State Board of Agriculture, says free rural mail delivery means bringing the country into quicker, easier, and more direct communication with the rest of the world, and more contentment to the farmer. Mr. Stockwell thinks it strange that rural delivery has been so long delayed, and suggests that 3 to 9 mail deliveries a day in the city as compared with none in the country is a discrimination against the latter; foreigners in the city are served at least 3 times a day, while native citizens in the country, who help to pay for the service, must get their mail as best they can at their own cost and inconvenience. Mr. Stockwell suggests that electric railways be used for carrying the mails to country homes. He regards free mail delivery as the imperative demand of the times, and declares it is the duty of the Government to broaden the service. (904.)

Mr. GREELEY, of South Dakota, predicts that rural delivery will prove one of the greatest blessings and educators ever brought to the back-country farmer; and declares that its value can not be overestimated. It not only helps to make the farmers more content, but enables an excellent class from the towns and cities to make permanent homes in the country—a class who would never do so without regular mails. (944.)

4. Postal savings banks.—Mr. GREELEY, secretary of the Board of Regents of Education of South Dakota, declares that nothing could help the common wage-earner more than well-established postal savings banks. He has known many a man who could not be induced to save a dollar because he knew of no safe way to keep it in small amounts. He has urged not a few young men to save, who promptly showed accounts with banks which had failed, and declared that they would not try again. (944.)

Mr. BRIGHAM says the National Grange is on the whole in favor of postal savings banks. The only objections are that it would take capital out of the community, and that there might be difficulty in investing it. (27, 28.)

Mr. STOCKWELL thinks that there is a feeling among the farmers of Massachusetts in favor of postal savings banks, but that they are not so interested in the matter as formerly. The banking facilities in Massachusetts are excellent. (904.)

CCCLXXX THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. HAMMOND, a cotton planter of South Carolina, thinks that secure savings banks, perhaps postal savings banks, would do much to educate and elevate the negro. (839.)

5. **Direct election of Senators.**—Mr. JONES says the National Grange is in favor of the direct election of Senators. Since the experience of 1899, when legislation was stagnated in many States, there seems to him to be little need for argument. (32.)

XIX. TAXATION.

A. Indirect taxes.—1. **How the tariff affects the farmer.** (See also *Sheep husbandry*, IX E 3, p. CCXXXVI; *Tariff on sugar*, X 4, p. CCLXXI.)—Professor BAILEY, of the College of Agriculture in Cornell University, says that the protective tariff is of less value to farming than to manufacturing, and this may be one reason of the inequality between the two businesses. What benefit the farmer secures from tariff protection is largely indirect. Yet "it is difficult to believe that protection can be assigned as a cause of any general agricultural decline, for the farmer has shared in whatever general prosperity the tariff protection may have brought." (1011.)

Mr. NALL, Commissioner of Agriculture of Kentucky, is of the opinion that agriculture has not had some of the advantages of legislation that manufacturing and some other lines of business have had—tariff legislation, for instance. He is inclined to believe that the tendency of protection has not been toward the agricultural classes. Mr. Nall has always favored reasonable encouragement to other lines of business, believing that the establishment of factories helps the farmers within reach of them, but he is inclined to think with the people of Kentucky that Congress has gone a little too far in most instances, and that the tariff duties have had a depressing effect on agriculture. (809.)

Mr. POWERS knows of no direct protection to the farmers. To catch certain voters a nominal tariff is put upon certain agricultural products brought in from other countries. It may affect prices a trifle on the border, but generally speaking prices are not affected. In so far as the tariff develops home markets and brings people into the country, however, it is an indirect protection, without which the farmer would feel the world competition under very much worse conditions. Mr. Powers says the tariff on steel rails is of as little consequence to-day, when steel rails are exported, as the tariff on farm products. (176.)

Mr. STOCKWELL, of Massachusetts, says the farmers have been and are generally in favor of a protective tariff for the benefit of the people and to encourage industries, but not to build up oppressive combinations of capital and giant monopolies. The farmers of New England gain somewhat from the protective tariff on agricultural products imported from Canada and the provinces, particularly hay and potatoes; and also from the tobacco tariff. Yet, on the whole, Mr. Stockwell considers protective legislation injurious to the farmer, increasing the prices of what he has to buy and of labor, thus more than offsetting the advantage he receives from a better home market. (901.)

Mr. WEDDERBURN, master of the Virginia State Grange, does not believe in a protective tariff. He objects to "protecting the manufacturer and making the farmer pay the bill and letting him scuffle for his price on his product." If manufacturers are to be protected, the farmer should have an equal protection that would enable him to buy the manufactured products. Mr. Wedderburn does not believe there is any farm product except wool that has any protection. The duty on tobacco does no good because this country exports hundreds or thousands of pounds for every pound imported. Mr. Wedderburn is familiar with the fact that there are tariff duties on certain agricultural products from abroad, but says that in the case of the great staples which are exported, such as wheat, a tariff of \$5 a bushel would not amount to any more than no tariff at all, because the price is fixed at Liverpool, the central market of the world, and the price paid in this country is the Liverpool price less the cost of transportation to Liverpool. The tariff on vegetables practically amounts to nothing, because transportation is so an important a feature. No tariff has been put on cotton, although cotton is imported from Egypt in sufficiently large quantities to materially reduce the price of sea-island cotton. Mr. Wedderburn believes that if one class of people is to be protected all should be. If there is going to be a duty on anything he would favor a duty on long staple cotton. (625-627, 631.)

Mr. Wedderburn complains of the high prices the farmer is obliged to pay for his purchases. He has had to pay for protected products more than their real value, and has had to sell at prices fixed in the world's markets. There has been an advance of 75 to 80 per cent in 2 years in the price of plows, and of every manufactured product, so far as he is able to discover, coming under the the protective-tariff laws.

Everything that is protected has a fictitious value put upon it, and the consumer pays the tax. (624, 627.)

Mr. BURKE, editor of the *Farmer's Voice*, says a purchaser of an article subject to tariff pays the tariff tax, plus interest and profit. (195.)

Mr. BROWN, president of the Georgia State Agriculture Society, thinks that possibly the tariff is too high, but that it alone can not have any great effect in depressing agriculture in Georgia. The greater part of the goods which the Southern planters buy are manufactured in this country; many of them are not subject to tariff. He believes, however, that the tariff on cotton manufactured articles imported from Europe is really paid by the planters in this country. (60, 64.)

Mr. HALE, of Georgia and Connecticut, believes that in all our tariff laws, with the exception of the McKinley tariff, protection was given to everyone else at the expense of the farmer. Under the McKinley law the protection was more equal. The farmers are willing to stand on an equality with the others. If others have protection they want it also. (397.)

Duty on hides.—Mr. GHEELRY, of South Dakota, thinks the duty on hides helps the cattle raisers materially at present. (942.)

Sugar and rice.—Dr. STUBBS, says the sugar crop of Louisiana amounts to only about one-seventh of the consumption of the United States, and the present rice production of Louisiana, Texas, Carolina, and Georgia is less than half the consumption of the country; hence the tariff is of great value to both sugar and rice producers, though it will be years before they can hope to supply the home demand. (773.)

Mr. POWERS believes that if the import duty were removed from sugar the people would use more sugar and get it cheaper. (177.)

Protection to California products.—Mr. NAFTZGER testifies that the Mediterranean fruits pay a duty of 70 cents a box and 30 cents freight, putting them practically on a par with the California fruits, which have to pay \$1.05 a box for freight; there is a differential of 5 cents against the California, and 30 cents additional if they are refrigerated. The Californians claim that the lemons grown in that State are better than the Mediterranean lemons. They are seedless, while the foreign fruit has a great many seeds. A chemical test was recently made and decided in favor of the California lemons. The Mediterranean lemons have rather a thicker skin because they are not cured; the California lemons are sweated down after they are taken from the trees. They run on an average larger than the foreign lemons. The Italian lemons are often shipped much smaller than 300 to the box. (959.)

Mr. NAFTZGER thinks the existing tariff duties should not be reduced, either by legislation or by treaty. The existing duties give California an advantage on several items, such as wines, olives, raisins, prunes, walnuts, and almonds; but the reduction proposed in the French treaty would work a hardship to the fruit interest, as would also the Jamaica treaty. (965.)

So far as Mr. TURNBULL is informed, the people of California do not wish the tariff to be lowered in any case, by reciprocity treaties or otherwise. (987.)

2. Protective duties proposed for the benefit of agriculture.—Mr. COLES, a farmer and dairyman of New Jersey, considers it necessary to give agricultural products all the protection possible. He mentions wool and hides in particular as articles on which a higher tariff is needed. He says that between three and four hundred million dollars' worth of agricultural products are imported which should be produced in this country. Nearly everything that can be grown in this country should be encouraged as manufactures have been encouraged, and this would help to diversify agricultural products. (123.)

Hemp.—Mr. NALL says the farmers of Kentucky complain of the competition with foreign-grown hemp, manila, sisal, and jute being admitted free of duty. Hemp is grown in the blue-grass region, but the product has fallen from 21,000,000 pounds to 4,000,000 pounds. Mr. Nall does not think that all the falling off is due to the competition of foreign hemp, because burley tobacco took up a good deal of the hemp land; but the farmers complain that they can not compete with the Sisal hemp and Manila hemp or jute and jute butts, introduced free of duty. The reduction from 21,000,000 to 4,000,000 or 5,000,000 pounds has not increased the price, but has probably kept it from falling flat. The Kentucky-grown hemp went to New York, Boston, etc., and was used for cordage and domestic twine. Mr. Nall thinks the demand was diminished by the invention of iron ties for cotton. A great deal of hemp tow was once used for making cheap twine and rope for binding wheat and baling cotton, but it is not now used for those purposes. There has been a substitution of Sisal and Manila hemp, especially for twine binders; and jute is used for twine and jute butts for bagging. For binding twine the Kentucky hemp has been superseded by the Sisal, out of which a cheaper twine is made. To this, Mr. Nall thinks, is partially due the diminished hemp acreage of Kentucky, affecting injuriously not only the

CCCLXXX THE INDUSTRIAL COMMISSION:—AGRICULTURE.

Mr. HAMMOND, a cotton planter of South Carolina, thinks that secure savings banks, perhaps postal savings banks, would do much to educate and elevate the negro. (839.)

5. **Direct election of Senators.**—Mr. JONES says the National Grange is in favor of the direct election of Senators. Since the experience of 1899, when legislation was stagnated in many States, there seems to him to be little need for argument. (32.)

XIX. TAXATION.

A. Indirect taxes.—1. **How the tariff affects the farmer.** (See also *Sheep husbandry*, IX E 3, p. CCXXXVI; *Tariff on sugar*, X 4, p. CCLXXI.)—Professor BAILEY, of the College of Agriculture in Cornell University, says that the protective tariff is of less value to farming than to manufacturing, and this may be one reason of the inequality between the two businesses. What benefit the farmer secures from tariff protection is largely indirect. Yet "it is difficult to believe that protection can be assigned as a cause of any general agricultural decline, for the farmer has shared in whatever general prosperity the tariff protection may have brought." (1011.)

Mr. NALL, Commissioner of Agriculture of Kentucky, is of the opinion that agriculture has not had some of the advantages of legislation that manufacturing and some other lines of business have had—tariff legislation, for instance. He is inclined to believe that the tendency of protection has not been toward the agricultural classes. Mr. Nall has always favored reasonable encouragement to other lines of business, believing that the establishment of factories helps the farmers within reach of them, but he is inclined to think with the people of Kentucky that Congress has gone a little too far in most instances, and that the tariff duties have had a depressing effect on agriculture. (809.)

Mr. POWERS knows of no direct protection to the farmers. To catch certain voters a nominal tariff is put upon certain agricultural products brought in from other countries. It may affect prices a trifle on the border, but generally speaking prices are not affected. In so far as the tariff develops home markets and brings people into the country, however, it is an indirect protection, without which the farmer would feel the world competition under very much worse conditions. Mr. Powers says the tariff on steel rails is of as little consequence to-day, when steel rails are exported, as the tariff on farm products. (176.)

Mr. STOCKWELL, of Massachusetts, says the farmers have been and are generally in favor of a protective tariff for the benefit of the people and to encourage industries, but not to build up oppressive combinations of capital and giant monopolies. The farmers of New England gain somewhat from the protective tariff on agricultural products imported from Canada and the provinces, particularly hay and potatoes; and also from the tobacco tariff. Yet, on the whole, Mr. Stockwell considers protective legislation injurious to the farmer, increasing the prices of what he has to buy and of labor, thus more than offsetting the advantage he receives from a better home market. (901.)

Mr. WEDDERBURN, master of the Virginia State Grange, does not believe in a protective tariff. He objects to "protecting the manufacturer and making the farmer pay the bill and letting him scuffle for his price on his product." If manufacturers are to be protected, the farmer should have an equal protection that would enable him to buy the manufactured products. Mr. Wedderburn does not believe there is any farm product except wool that has any protection. The duty on tobacco does no good because this country exports hundreds or thousands of pounds for every pound imported. Mr. Wedderburn is familiar with the fact that there are tariff duties on certain agricultural products from abroad, but says that in the case of the great staples which are exported, such as wheat, a tariff of \$5 a bushel would not amount to any more than no tariff at all, because the price is fixed at Liverpool, the central market of the world, and the price paid in this country is the Liverpool price less the cost of transportation to Liverpool. The tariff on vegetables practically amounts to nothing, because transportation is so an important a feature. No tariff has been put on cotton, although cotton is imported from Egypt in sufficiently large quantities to materially reduce the price of sea-island cotton. Mr. Wedderburn believes that if one class of people is to be protected all should be. If there is going to be a duty on anything he would favor a duty on long staple cotton. (625-627, 631.)

Mr. Wedderburn complains of the high prices the farmer is obliged to pay for his purchases. He has had to pay for protected products more than their real value, and has had to sell at prices fixed in the world's markets. There has been an advance of 75 to 80 per cent in 2 years in the price of plows, and of every manufactured product, so far as he is able to discover, coming under the the protective-tariff laws.

the support of the county and township governments are levied upon real estate, horses, and cattle. There is also a small tax on dogs which goes to reimburse persons whose sheep have been killed, when it is impossible to find out whose dog did the killing. The State returns to the county three-fourths of the tax received on money at interest. Property is assessed by elected assessors, and the valuations revised by the county commissioners, after opportunity for appeal. The township boards of road supervisors, school directors, and overseers of the poor fix the amount of tax to be levied for roads, schools, and care of the poor, respectively, so that the township is maintained by taxes levied by its own officers. The tax for ordinary school purposes is limited to 10 mills, and there is also a limit for the road tax, but the road supervisors can get around it by running the township into debt. Real-estate assessments are made once in 3 years. (352, 354.)

Mr. Hamilton testifies that the assessment of real estate in Pennsylvania varies from one-fourth of the value to more than the property is worth, according to the judgment of the assessors. He has known of property divided by a township line, one part of which was assessed twice as much as the other, though they were as nearly alike as possible. The tax rate differs according to the pleasure of the several township boards. It may reach 30 mills, or it may be only 3 or 4 mills. The county rate is fixed by the board of county commissioners, and is usually from 3 to 5 mills. The State taxes are fixed by statute. (353.)

Mr. Hamilton testifies that the officers who make the assessments are elected, and frequently their intention as to raising or lowering the valuation is known before the election. In many cases it is understood that a candidate, if elected, will lower valuations, or if there are large property interests in a locality held by comparatively few persons and the large majority of voters hold small amounts of property, the chances are that the pledge will be made that values shall be raised.

Mr. Hamilton believes that 3 assessors, selected because of their good judgment and integrity, should be appointed in each township by the court. Then the assessments throughout the county should be revised and equalized by a body composed of one man from each township board of assessors instead of by the county commissioners, who have no knowledge of the situation in the various localities. There should be a right of appeal to the board of county commissioners with opportunity for the aggrieved taxpayer and the assessors to be heard. (357.)

Ohio.—Mr. MILLER, secretary of the State board of agriculture, says that in Ohio values are fixed by township and district assessors. Real estate is assessed once in 10 years and personal property annually. Some very incompetent men are elected assessors, and they doubtless favor their friends sometimes. Appeal lies to the county board of equalization, but appeals are not made, as a rule. Many owners of intangible property refuse to answer the questions of the assessor, in which case the assessor makes such return as he can from the information he can secure and adds 50 per cent as a penalty. Most owners of intangible property let this stand, but often a property owner makes affidavit that it is too high and makes his own returns, which is in many cases accepted. A tax commission recently found that a very considerable part of the intangible property was not placed on the tax rolls. Mr. Miller thinks the trouble is laxity in the execution of the law. (611, 612.)

Mr. Miller says that Ohio has for a few years past had a tax-inquisitor law. The counties are authorized to employ a man to investigate the holdings of the citizens of the county, and if he finds that they have been escaping taxation report the amount to the auditor. Large amounts of property have been discovered through these inquisitors. Mr. Miller thinks Ohio has no State inspection of taxes, but there is a State Board of Equalization. (612.)

Illinois.—Mr. BURKE testifies that the taxation of personal property in Illinois is governed by a new law. The taxpayer renders his own statement on a schedule, subject to revision by the board of review. Taxation of personal property was increased about 46 or 47 per cent by this law. (195.)

Mr. Wilson testifies that land is assessed in Illinois every 2 years, and new improvements may be added each year. (248.)

North Dakota.—Mr. FROM says that in North Dakota property is valued by the assessor, and then a levy is made to meet the expenses of the different counties. The tax is supposed to be on the actual value of the property. It is upon the assessed value, which is a great deal below the actual value. (791.)

South Dakota.—Mr. GREELEY says the aim in South Dakota seems to be to assess property at about two-thirds the value, or possibly less. The rate of taxation is fixed by the county board, and the assessments are equalized by the State Board of Equalization. (935.)

Maryland.—Mr. AGER says there is no regular period for general reappraisal in Maryland, and the only general assessment within 20 years was that of 1897. During the regular assessments only new improvements are noted.

Mr. Ager illustrates the working of this system as follows: "When I first came to Hyattsville I had 20 cows and 3 horses. The treasurer came and took down the amount of stock I had. I paid tax on that for 10 or 15 years, while I had double that amount a good deal of the time." (111, 112.)

Virginia.—Mr. WEDDERBURN thinks the State tax in Virginia is between 40 and 50 cents on \$100. The total tax in Fairfax County is about \$1.30; in Alexandria County it is in the neighborhood of \$2. The county tax is levied by the board of supervisors, all of whom are farmers in Fairfax County. Property is assessed once in 5 years, very reasonably and low. The State tax is equally borne by all the property of the State; no discrimination is allowed under the constitution. A committee recently sent out circulars for information about the amount of taxation levied in the various counties and townships of Virginia. Returns were received from about 33 counties, showing that the taxes for county and township expenses in these counties were very nearly \$1,000,000—nearly three times as great as in any 33 counties in North Carolina. Mr. Wedderburn thinks there are too many officeholders. At Fairfax Court-house there is a county treasurer, a board of supervisors, magistrates, 2 assessors, and other officials. (621.)

Mr. Wedderburn thinks taxation the burning question in Virginia, and the real reason for calling the constitutional convention. He thinks the convention would not have been called on account of the suffrage question alone. The strongest white district went strongest against the constitutional convention, and the strongest black district went strongest for it. (621, 622.)

West Virginia.—Mr. CLOHAN testifies that the rate of State taxation in West Virginia is 35 cents on \$100. The county rate is fixed by the county court, composed of three elected Commissioners. In Berkeley County the county tax is 45 cents. The heaviest tax is a district-school tax, fixed by the school commissioners. There is also a road tax laid by the county court but levied on the districts according to their needs. One district may pay 10 cents, another 15, and another 20. (599.)

Kentucky.—Mr. NALL says the Kentucky rule is to value property for what it would bring at a fair voluntary sale. The assessor is looked after by the board of supervisors in each county, and there is also a State Board of Equalization. Until recently the railroads have largely escaped taxation, but since they have been put into the hands of the Railroad Commission there is not so much complaint on that score. (811.)

North Carolina.—Mr. WHITE thinks the taxes are fair and equitable in North Carolina. There is an income tax on salaries and wages which some have grumbled about, but Mr. White thinks it nothing more than right. (432.)

Tennessee and Mississippi.—Mr. NORFLEET testifies that the rate of taxation is over 3 per cent in Memphis and about 3 per cent on agricultural lands in the Delta. In the front counties about 17 mills constitute the levee tax, and the remaining 13 the State and county tax. Open land is assessed at \$8 to \$12 per acre. There is also an acreage tax of 5 cents an acre. (489.)

Desert lands in California.—Mr. NAFZGER testifies that the desert lands of California are valued at an extremely low rate, but he thinks they are usually taxed in proportion to their value with other property. (951.)

2. Taxation of mortgages.—*Vermont.*—Mr. SPEAR testifies that there has been a great deal of dissatisfaction in Vermont during the past decade over the taxation both of mortgages and of mortgaged real estate. This double taxation is a heavy burden upon the farmers who are in debt for their holdings. (407.)

West Virginia.—Mr. CLOHAN, a farmer of West Virginia, declares emphatically that taxation is the most serious matter the farmers have to contend with. The practice in West Virginia is to make real estate bear the whole burden of taxes. If a man buys a farm for \$10,000 and puts only \$2,500 into it, he must at once pay taxes on the whole value of the farm. When the farmer borrows money he has to pay 6 or 7 per cent, because the lender will tell him he has to pay 1½ cents county tax, and must put up the interest to cover that amount. As a matter of fact, though the laws call for the listing of evidences of indebtedness, they are not listed. The assessor is generally a candidate for reelection, and does not want the enmity of the money lender, who is generally an influential man. When the assessor finds the creditors they refuse to list their notes and securities, and he can not levy a tax on notes and mortgages unless he can see them. When the assessor comes to Mr. Clohan's farm, Mr. Clohan says to him: "There are the horses, there are the cows and everything; you value them;" but a man does not open his desk and show his mortgages, notes, and bonds. The farmer pays the tax on real estate, and pays the tax over again to the lender. (598, 599.)

Ohio.—Mr. MILLER, of Ohio, says "the owners of the intangible property actually own their property, while the man who pays the taxes on his real estate is paying for the privilege of calling it his own at some future time." (613.)

3. Taxation of corporations.—Exemption of the telephone monopoly in Massachusetts.—Mr. STOCKWELL testifies that by the charter granted by Massachusetts to the telephone company many years ago the stock is exempted from taxation to the amount of about \$50,000,000. The company protects its monopoly by covering the ground so that nobody else can get a foothold. The ground is so well covered that competing companies can not offer sufficient inducements so that cities will allow a second line of appliances. A competing company has been laying wires in Boston, but when they attempted to get the same right in Worcester the conditions were so hard that they had to give it up. Mr. Stockwell thinks it the duty of the State or nation to cease to protect any corporation which receives an undue proportion of the profit of that protection and does not share it with the people. Mr. Stockwell's impression is that certain industries export products and sell them abroad at a lower price than at home. In such cases he says the tariff should be taken off, and if exemption from taxation has been granted it should be revoked. (897, 898.)

Assessed value of the property of corporations in New York.—Mr. DEVO, Secretary of the Board of Tax Commissioners of New York, says that he has succeeded in separating the assessments of the property of corporations from other assessments, and finds the proportion surprisingly small, ranging from 12 per cent of all assessed values in New York County to 31 per cent in Schenectady, and averaging 14½ per cent for the State. This includes steam railroads, 3.47 per cent; street railroads, 1.6 per cent; telephone and telegraph companies, 0.25 per cent; gas, electric-light, and power companies, 1.15 per cent; banks, 2.73 per cent; and miscellaneous, 5.33 per cent. (1000.)

Mode of assessment in Ohio.—Mr. MILLER testifies that in Ohio each railroad corporation is assessed by a board composed of the auditors of the counties through which the railroad extends. The practice is to assess the company so much a mile for the main track, so much a mile for side tracks, so much for termini and improvements, and so much a mile for rolling stock. Mr. Miller does not think this is an equitable method of taxation as it is conducted, and believes in a general rather than in a local method of taxing railroads. He thinks the Nichols law applied to railroads would be very much more successful than the present law. (613.)

The Indiana plan.—Mr. AARON JONES says the railways in Indiana have always been taxed on the value of their property, but about 10 years ago the new plan was begun of having that value ascertained by the State Board of Equalization and apportioned among the separate localities. The effect has been to increase the railway assessments from \$66,206,000 to \$161,039,000. The actual selling value of the visible property is sought by taking account of the market value of the capital, the earnings, etc. Every minute item of property owned by the railways must be scheduled. The witness considers this system just and satisfactory.

Palace cars, telegraph and telephone lines are assessed in essentially the same manner, and the assessment has been largely increased by doing so. (35, 36.)

Mr. BRIGHAM says the valuation of railways in Indiana is about double per mile that in Ohio. Pennsylvania raises practically all its State revenue from corporations; there is no direct State tax on land. (16.)

4. Occupation tax in Pennsylvania.—Mr. HAMILTON says there is an occupation tax in Pennsylvania, levied under the assumption that the constitution forbids taxing except under a classification, so that the tax must be low enough to make it possible for the most impecunious lawyer, for instance, to pay it. In a certain county lawyers are put down at \$250, and if the rate is 1 mill the lawyer is taxed 25 cents, though his income may be \$10,000 or \$20,000. In this county physicians are taxed at \$200; ministers at \$75; county superintendents at \$250; professors of colleges and academies at \$250; superintendents of high schools at \$200; common-school teachers at \$50; merchants at \$200; shopkeepers at \$100; clerks at \$100; mechanics at \$100; apprentices at \$50; bosses and foremen at \$75; civil engineers at \$250; surveyors at \$150; bank presidents at \$400; bank cashiers at \$250; county officers at \$250; president judge at \$300. The law gives the president judge a salary of \$4,000. Farmers do not pay an occupation tax in Pennsylvania. (353.)

Mr. Hamilton thinks it would be possible under the constitution of Pennsylvania to classify occupations according to the amount of business done or the income. (355.)

C. Taxation of agricultural property.—1. Overtaxation of the farmer.—Mr. POWERS says there is no question that the farmer, of all classes in the United States, has the least chance of escaping taxation. In New York State the city people pay, in proportion to their wealth and ability, only one-third of what the country people do; and it is but just that large sums are raised in the cities to support the country schools. Taxation in cities involves heavier expenses than are common in the country, but the people paying them have special advantages. There are many

CCCLXXXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

so-called taxes in cities—as for sidewalks, water, and sewers—charged against the abutting property, which are really not taxes, but investments under the name of taxes. (185.)

Mr. GEORGE, of Chicago, thinks that the farmers of the United States pay considerably more than their fair share of taxes, their visible assets being subject to assessment at all times. (221.)

Mr. W. H. BURKE, editor of the *Farmer's Voice*, says that in cities property is hidden, but the property of the farmer is visible. An average Chicago man worth ostensibly \$10,000 will spend more money in a month than a farmer worth \$10,000 will in a year. He will have more personal property than the farmer will, but much of it will be so minute as to escape the assessor. Even where property can not be hidden, Mr. Burke thinks there are good grounds for believing that assessors are influenced in their estimates. He has known the property of the Pullman Car Company to be assessed ridiculously low. (194.)

Referring to a series of articles published in the *Chicago Times* early in 1897, showing inequalities and discriminations in assessments, Mr. Burke says the assessed valuation of Chicago at that time was about \$77,000,000 less than in 1878, when the population was only about 350,000. (200.)

Mr. Burke cites a pamphlet by Mr. Lawson Purdy as authority for the following statement: In Monroe County, N. Y., containing the city of Rochester, the assessed valuation of real estate is more than double that of Oneida County, though the personal property assessment in Oneida County is nearly double that of Monroe County. In the four city counties of Missouri personal property amounts to 15½ per cent of the total assessed valuation, and in the remainder of the State 29½ per cent. In St. Louis personal property amounts to 14½ per cent of the total valuation, and in Camden County, a typical farming county, it amounts to 37 per cent. Mr. Purdy is quoted as saying that it does not appear that taxes on personal property benefit the farmers in Missouri. (193, 194.)

Professor DAVENPORT says all the farmer's property is open to inspection. The assessor is one of his near neighbors, who knows exactly how much land and personal property he has, and what it is worth. As an assessor, Professor Davenport has succeeded in finding a \$100 note, which would be ridiculous in a city. He says it is much more difficult to get at the personal property of any other profession than that of a typical farmer. (226.)

Mr. NORFLEET, a cotton factor of Memphis, thinks there is not much ground for the claim that real-estate taxes are heavier in the country than in the towns, but the personal property of farmers is more exposed, and they pay more fully on what they own than those pursuing other occupations. Speaking with special reference to Mississippi and Tennessee, he says property is assessed on the same basis in city and country, at about 40 to 60 per cent of the value (perhaps about one-third in some instances), according to the conscientiousness of the owner and his particular friendship with the assessor. (489.)

Professor BAILEY, of Cornell University, thinks the farmer is taxed relatively too high, but the amount of excess is so small as compared with the earning power of the investment that it can scarcely be regarded as contributing, in any large degree, to agricultural decline. (1011.)

New England.—Mr. BACHELDER believes that farm property in New England is assessed at higher rates than city and village property. Many farms remain on the tax list at rates fixed many years ago, when they were more fertile and valuable. (43.)

It seems very clear to Dr. CROWELL that the rate of taxation on farms in many States is too high. In Massachusetts farm land is assessed at \$1,000 which will sell for \$600 or \$700, so that the rate of taxation is much higher than where property sells a good deal above its tax valuation; consequently people are not going to invest in rural real estate. Dr. Crowell thinks real estate, especially rural real estate, is bearing too large a burden of taxation. (341.)

Mr. STOCKWELL says the farm is seen and taxed; there is no escape; but probably from 1,500 to 2,000 millions of intangible wealth escapes taxation in Massachusetts. If this were remedied it would lower the taxation of the farm very greatly. The double burden falls on the productive industries, and most heavily on the farmer.

The school tax is not entirely for the benefit of the town, but of the State, and the roads are not entirely for the benefit of the town, but of the traveling public; yet the taxes for these purposes are on the town. The removal of industries, population, and wealth makes this a heavy burden.

Mr. Stockwell says Massachusetts has the best corporation laws of any State, and honest returns are enforced; but Massachusetts people desiring watered stock or a little fraud step into the adjoining States and come back with a Maine, Delaware, or the New Jersey charter. So Massachusetts business is carried on in Massachusetts

cities and towns free from control of the State tax commissioner, and contributing nothing, though receiving all the advantages and protection of the laws of the State.

These, Mr. Stockwell says, are three of the ways in which taxation has fallen very heavily on the farmers. (888, 889.)

Mr. Stockwell adds that in the western part of Massachusetts the ordinary farmers dependent upon their farm crops have been found to be really oppressed by taxation, because wealthy residents demand so many improvements and the town is obliged to do so much. The farmers are proud of the town, but want some relief from the taxation that is driving them away. Lenox is a great summer resort for wealthy New York people, but Mr. Stockwell thinks the real estate valuation has not increased in consequence of their improvements as it should have done. (889, 890.)

Mr. Stockwell testifies that real estate in the farming communities of Massachusetts is in some cases valued for more than it would bring at forced sale. (889.)

Mr. Stockwell says there is no greater crime in Massachusetts than the exemption of the rich and the double taxation of the poor. There are indirect taxes—tariff duties and trust monopolies—and direct taxes caused by the exemption of \$15,000,000 of wealth. Mr. Stockwell quotes a well-known gentleman as saying, "The poor always have paid the taxes and they always will." (889, 898.)

New York.—Mr. Devo, secretary of the New York Board of Tax Commissioners, says that the only subdivisions of his State for purposes of taxation are cities and towns. There is no separation of farm lands from village property. While the local assessors generally declare that they assess property at its full value, this is not accepted as a fact. The State board equalizes assessments for State taxes, according to the proportions which the assessed values bear to the real values, as nearly as they can be ascertained. It is the opinion of the commissioners that farm property is generally assessed more nearly at its real value than city property. The reason is believed to be that farm lands have greatly declined in value. It is also believed that property worth, say, from \$1,000 to \$5,000 is assessed most nearly at full value, and that the more expensive buildings, both residences and manufacturing or business property, usually bear the lowest relative assessment, both in the city and in the country. (990, 1000.)

In reply to a question concerning the taxation of agricultural property, Mr. NORRIS, master of the New York State Grange, expresses the opinion that landed property pays an unfair tax as compared with personal property, real estate being visible, while money is put into the form of bonds or concealed. He thinks the fault is largely in the enforcement of the law. (326, 331.)

Mr. Norris says there has perhaps been as much discussion of taxation in the granges of New York as of any one subject. The farmers are of one mind that land pays an unfair proportion of the taxes. Some are in favor of exempting personal property, but others favor taxing it. (329.)

Mr. BURKE refers to an inquiry into taxation as affecting farmers in four counties of New York, instituted by the United States Department of Agriculture in 1896, which showed that the farmers bear a large proportion of the taxes. (193.)

Mr. WIERING does not think that the farmers in New York are disproportionately taxed. The average farm of 100 acres pays a tax not exceeding \$25. He does not think that this amount can make the difference between good times and hard times to the owner of such a farm. (994.)

Professor BAILEY, of Cornell University, quotes a letter from a representative New York farmer, in which it is stated that an ordinary farm of 100 acres has to pay taxes amounting to not far from \$70 a year. (1007.)

New Jersey.—According to Mr. DYE, secretary of the New Jersey State Board of Agriculture, the methods of assessing property in different parts of New Jersey are lacking in uniformity, although the State board of taxation, which was recently established, had an important influence in reducing this evil. Practically all farm property is assessed while other forms of property escape. The taxation of corporations of different kinds has been sufficient since 1884 to cover the expenses of State government, except the State school tax, but the local taxpayers do not profit by this tax. There is a project now on hand, in view of the increase of State taxes, to distribute part of them among the counties. The average tax rate for all classes of governments in the State in 1897 was \$1.78 per \$100. In the urban counties, where the average assessment is 60 per cent of the true value, the rate was \$2.13; in the agricultural counties, where the property is assessed at full value, the average was \$1.26. (90, 91.)

Mr. COLES considers the tax laws about as equitable as they can be made, but complains that some officers do not do their full duty in executing them, so that sometimes taxes are not properly equalized. Everything in agriculture can be seen by the assessor, while in some other occupations the property can be concealed. (128.)

Mr. KETCHUM, of Mercer County, N. J., says the valuation of farm land in that county is higher than that of city property. In some instances a hardship results

CCCLXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

from the farmer's own persistence in putting too high a value on his property. He does not reconcile himself to the shrinkage in values, especially if his farm is for sale. On the other hand, some farm land is occasionally rated too low by the assessor, especially if he wants to be reelected. The rate of taxation of agricultural property varies from \$1.38 to \$1.45, as compared with about \$2.50 in Trenton. (134.)

Pennsylvania.—Mr. HAMILTON believes that real estate holders, including farmers, are taxed out of all proportion to other classes of business men in Pennsylvania. Mr. Hamilton thinks that real estate bears too much taxation, and that some other things are taxed too lightly. With the development of business most of the people are employed and receive salaries, some of them very large, and the amount of their tax is almost nothing. Mr. Hamilton knows of men who get salaries of \$5,000 a year whose road tax is 75 cents, while a common day laborer in the same community pays a road tax of \$1.80. There are judges of courts who get salaries of \$4,000 or \$5,000 who pay a tax of \$300, while a man who owns a house worth \$2,000 or \$3,000 will be taxed upon its full value, though he may have no income whatever and may be in debt for the property. Merchants who do a large business pay almost no tax on their occupation. The tax on a farm property worth \$6,000, at a 10-mill rate, is \$60 a year, though the farmer's income from the investment, after his own labor is paid for, would perhaps not be over \$300, and if there is a failure of crops the tax must come out of the original property or other funds. A man with a salary of \$5,000 a year would pay only \$3 as a 10-mill tax on his occupation. The salaried man who invests his salary in a mortgage on a farm pays a 4-mill tax to the State, and if he puts his money into a farm he will pay, on an average, a 10-mill tax. The effect of the difference is to keep men from buying farms. Mr. Hamilton says it was equitable at the origin of the Government to make real estate bear the burdens of government, but the system has not been adjusted to meet new conditions. (355, 356.)

Mr. Hamilton says that in 1890 Secretary Edge, of the Pennsylvania State Board of Agriculture, collected statistics of actual sales of farm property in the State and the tax paid by each piece of property. The number of farms returned was 556 in 48 counties; they had been sold for \$4,225,805, and paid a tax of \$40,282.65. The rate, not deducting the tax on farm animals, which is comparatively insignificant, was 9.50 mills, and after deducting the personal property was 8.66 mills. Mr. Hamilton at that time made an examination of a county, omitting the boroughs, and found that the taxation on the actual value of the property, including horses and cattle, was 9.9 mills. In 1891 the secretary of the State board of agriculture collected statistics upon 8,081 farms, the estimated value amounting to \$51,525,929 and the taxes paid to \$440,317.96. In 1894 the property on the list was increased to 19,719 farms, and in 1895, 24,734, the total value being \$151,529,458 and the total tax \$1,259,847.17, or 8.3 mills. Examination by a different method showed that real estate in Pennsylvania, in country and city, at that time paid about 15 mills. (354.)

Ohio.—Mr. MILLER, secretary of the Ohio State Board of Agriculture, says the laws of Ohio require that all property shall be taxed at its actual value, but it is generally understood that property is not assessed for all it would bring under the most favorable conditions. Mr. Miller has no doubt that the farmers of the State pay an undue proportion of taxes, because securities are not placed on the tax list, while the farmer's property is exposed to view and can not escape the assessor's eye. (611.)

Mr. BRIGHAM believes that farmers pay relatively much more taxes than other classes. The real estate itself in the country is usually assessed higher than in the cities, especially where the same officer or authority makes the assessments in both. Certain wealthy taxpayers in the town usually see to it that a man is chosen as assessor who will be inclined to favor town property.

Personal property of farmers is assessed at from 40 to 50 per cent of its true value in Ohio, while other forms of personal property, merchandise, bonds and mortgages, bank property, etc., probably are not assessed above 15 per cent. This is not because the farmer is more honest, but because he can not secrete his property. It is not pretended in Ohio that any property is assessed at its full value; the assessment at the best is only from 40 to 75 per cent. But the farmer's personal property is almost all visible, and he is required to swear to a minute statement of his possessions. The assessor knows fairly well the value of the different articles. The merchant, on the other hand, gives a rough sum for his assessment, and usually very much below the true value of his stock, and the assessor is incompetent to correct it. Manufacturers of Ohio, under the law itself, were formerly exempt from taxation on their products on hand. It was shown a few years ago that some of the strong State banks were assessed at less than \$2,000. National banks can not escape so largely, since their books are open, but the courts in certain cases have held that their property could not be assessed at a higher rate than property around them. (14, 17.)

Indiana.—Mr. JONES confirms the opinions of Mr. Brigham as to the relatively excessive taxation of agricultural property, referring especially to the State of Indiana. He adds that the schedules of questions used in assessing personal property apply especially to farm property and are less detailed as to other classes. A uniform method of assessing personal property is desirable. Much evasion of taxation is justified by the taxpayers on the ground that assessments are so unequal. If a note is turned in at all it will naturally be at its full value, while merchandise, etc., are confessedly assessed much below real value. Taxes would be lowered by one-third if all property were assessed. Wealthy men do not always escape taxation, but securities of different kinds, which they largely hold, are frequently exempt from taxation or are not discovered.

The farmers are often without representation on State boards of equalization, and yet those boards are more familiar with the value of farm lands than of city property, and assess it too high. (34, 36.)

Illinois.—Mr. WILSON, master of the Illinois State Grange, says the farmers of Illinois are not satisfied with the system of taxation. The farmers are paying the greater part of the taxes—probably 78 or 79 per cent. The farmer can not conceal any property even if he is so inclined; it is all out under the assessor's eye. The farmers are not great money lenders, and their surplus is generally invested in real estate, stock, or something visible. The farmer gives an itemized account of all his property, and he is about the only man who does. The assessor asks the number of horses, cattle, hogs, and chickens, whereas in the city or village he asks the merchants the amount of their merchandise in one question. The bankers nearly escape personal property taxation. Mr. Wilson thinks if one man itemizes his property every other man should do so. (247, 248.)

Minnesota.—Mr. HANLEY believes farmers pay much more in taxes than they should, as compared with other industries. As a representative of the farmers before the Minnesota State board of equalization, he found that leading merchants and jobbers who were rated at \$1,000,000 and carried \$750,000 insurance stated that \$65,000 was all that they ought to pay taxes on. They said, "If you tax us, you will drive us out of this State." (278.)

South Dakota.—Mr. GREELEY, of South Dakota, knows of no intention that the farmer should be overtaxed, but says all the farmer has can be seen, and for that reason he pays more nearly on what he has than one who has his money invested otherwise. Many farmers feel that they are unfairly taxed. (935.)

Maryland.—Mr. AGER thinks agricultural property in Maryland and other States bears a heavier taxation in proportion to profits than any other property, because it is all visible, and a great deal of invisible property is never taxed. He believes many men will perjure themselves in returning their property for taxation when they would not in any other case. (111.)

Virginia.—Mr. WEDDERBURN, master of the Virginia State Grange, says the farmers in Virginia pay what would be called in other States a low tax rate. His opinion is that the farmer has the best of it, as compared with the merchant and manufacturer. Mr. Wedderburn does not believe in the Virginia system of licenses and taxes on manufactures. (621.)

Kentucky.—Mr. NALL considers the Kentucky tax law sufficient, but says the administration of it has failed to bear equally upon farming lands and other property. The farmer's land lies before the assessor, and is very apt to be assessed up to its full value, while a great deal of corporate and invisible property has escaped; but investigations are now bringing these out, and the evil may be corrected. The answers to Mr. Nall's inquiry on the subject indicate that agricultural lands bear more than their just proportion of taxation. (811.)

South Carolina.—Mr. HAMMOND, a cotton planter of South Carolina, says that the present weight of taxation on agricultural property is three or four times as great as it was a generation or more ago. The burden is endured without rebellion only because it is distributed among small taxpayers who do not realize it. "A charge of \$1 poll tax and of \$1 road tax is collected from a negro who has not a change of clothes, upon the penalty of putting him on the chain gang if it is not paid. The assessment valuation of property is preposterous, unequal, and unjust. When made by local boards of assessors all sorts of favoritism is shown." (827, 828.)

Georgia.—Mr. HALE declares that in Georgia and everywhere else real estate pays more than its share of taxation. The taxation of agricultural property in Georgia is on a par with other real estate. The rate of taxation is moderate. Mr. Hale suggests that it might be better if more taxes were raised and used for the public benefit. (387.)

Mr. PEEK says taxes on farms are pretty heavy in Georgia. The rate is about 6½ mills, and nothing on the farm can escape taxation. The assessments generally compare very well with the cash value. (460.)

CCCLXXXVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

from the farmer's own persistence in putting too high a value on his property. He does not reconcile himself to the shrinkage in values, especially if his farm is for sale. On the other hand, some farm land is occasionally rated too low by the assessor, especially if he wants to be reelected. The rate of taxation of agricultural property varies from \$1.38 to \$1.45, as compared with about \$2.50 in Trenton. (134.)

Pennsylvania.—Mr. HAMILTON believes that real estate holders, including farmers, are taxed out of all proportion to other classes of business men in Pennsylvania. Mr. Hamilton thinks that real estate bears too much taxation, and that some other things are taxed too lightly. With the development of business most of the people are employed and receive salaries, some of them very large, and the amount of their tax is almost nothing. Mr. Hamilton knows of men who get salaries of \$5,000 a year whose road tax is 75 cents, while a common day laborer in the same community pays a road tax of \$1.80. There are judges of courts who get salaries of \$4,000 or \$5,000 who pay a tax of \$300, while a man who owns a house worth \$2,000 or \$3,000 will be taxed upon its full value, though he may have no income whatever and may be in debt for the property. Merchants who do a large business pay almost no tax on their occupation. The tax on a farm property worth \$6,000, at a 10-mill rate, is \$60 a year, though the farmer's income from the investment, after his own labor is paid for, would perhaps not be over \$300, and if there is a failure of crops the tax must come out of the original property or other funds. A man with a salary of \$5,000 a year would pay only \$3 as a 10-mill tax on his occupation. The salaried man who invests his salary in a mortgage on a farm pays a 4-mill tax to the State, and if he puts his money into a farm he will pay, on an average, a 10-mill tax. The effect of the difference is to keep men from buying farms. Mr. Hamilton says it was equitable at the origin of the Government to make real estate bear the burdens of government, but the system has not been adjusted to meet new conditions. (355, 356.)

Mr. Hamilton says that in 1890 Secretary Edge, of the Pennsylvania State Board of Agriculture, collected statistics of actual sales of farm property in the State and the tax paid by each piece of property. The number of farms returned was 556 in 48 counties; they had been sold for \$4,225,805, and paid a tax of \$40,282.65. The rate, not deducting the tax on farm animals, which is comparatively insignificant, was 9.50 mills, and after deducting the personal property was 8.66 mills. Mr. Hamilton at that time made an examination of a county, omitting the boroughs, and found that the taxation on the actual value of the property, including horses and cattle, was 9.9 mills. In 1891 the secretary of the State board of agriculture collected statistics upon 8,081 farms, the estimated value amounting to \$51,525,929 and the taxes paid to \$440,317.96. In 1894 the property on the list was increased to 19,719 farms, and in 1895, 24,734, the total value being \$151,529,458 and the total tax \$1,259,847.17, or 8.3 mills. Examination by a different method showed that real estate in Pennsylvania, in country and city, at that time paid about 15 mills. (354.)

Ohio.—Mr. MILLER, secretary of the Ohio State Board of Agriculture, says the laws of Ohio require that all property shall be taxed at its actual value, but it is generally understood that property is not assessed for all it would bring under the most favorable conditions. Mr. Miller has no doubt that the farmers of the State pay an undue proportion of taxes, because securities are not placed on the tax list, while the farmer's property is exposed to view and can not escape the assessor's eye. (611.)

Mr. BRIGHAM believes that farmers pay relatively much more taxes than other classes. The real estate itself in the country is usually assessed higher than in the cities, especially where the same officer or authority makes the assessments in both. Certain wealthy taxpayers in the town usually see to it that a man is chosen as assessor who will be inclined to favor town property.

Personal property of farmers is assessed at from 40 to 50 per cent of its true value in Ohio, while other forms of personal property, merchandise, bonds and mortgages, bank property, etc., probably are not assessed above 15 per cent. This is not because the farmer is more honest, but because he can not secrete his property. It is not pretended in Ohio that any property is assessed at its full value; the assessment at the best is only from 40 to 75 per cent. But the farmer's personal property is almost all visible, and he is required to swear to a minute statement of his possessions. The assessor knows fairly well the value of the different articles. The merchant, on the other hand, gives a rough sum for his assessment, and usually very much below the true value of his stock, and the assessor is incompetent to correct it. Manufacturers of Ohio, under the law itself, were formerly exempt from taxation on their products on hand. It was shown a few years ago that some of the strong State banks were assessed at less than \$2,000. National banks can not escape so largely, since their books are open, but the courts in certain cases have held that their property could not be assessed at a higher rate than property around them. (14, 17.)

Mr. HALE believes there should be a uniform law in every State requiring the listing of all property once a year, under a very severe penalty. (387.)

Mr. NORRIS thinks that all classes of property should bear as nearly as possible an equitable proportion of taxes, either by a listing system or some other system. (326.)

Mr. HANLEY believes in taxing every article of property, visible or invisible, on its full cash value. He proposes that certificates of stock should not be transferable as legal assets unless stamped to show that the tax has been paid upon them. He believes uniform legislation necessary, because for individual States to undertake such taxation would drive people to other States. (278.)

Mr. MILLER says there are in Ohio a good many farmers' clubs which discuss taxation and other questions pertaining to agriculture. The farmers' organizations very generally believe that franchises and intangible property should be placed on the tax duplicate at their actual value. Mr. Miller believes that intangible property should be assessed according to its earning capacity. (613.)

Mr. NORFLEET is of the opinion that a very low rate of taxation should be fixed on personal property, so that it would come to the surface and be assessed. (489.)

Mr. BURKE thinks it a human impossibility to prevent deceit, perjury, and fraud under the present mixed system of taxation. The system is too confusing; no one mind is capable of grasping it. State officers might accomplish something, however, by consultation and adopting the best measures possible. (200.)

Appointment of assessors.—Mr. STOCKWELL testifies that in Massachusetts the assessors are elected by the people of the town. He thinks it would be far better if they were removed from the influence of the electors by being appointed. One man of prominence and wealth can assure the election of an assessor to his liking or endanger that of one who does his duty. The rich influence the assessors by threatening to leave the town and by putting the honest assessor out of office. (889.)

Mr. MILLER, of Ohio, thinks it would be an advantage to have assessors appointed instead of elected, if excellent men were appointed, because men who are elected assessors are greatly inclined to favor the voters of their districts. (611.)

Taxation of evidences of indebtedness.—Mr. CLOHAN suggests a twofold remedy: (1) He would allow the borrower to make a mortgage a matter of record and have the tax he pays credited on the interest due on his note. (2) He would also have any evidence of debt without the assessor's stamp showing that it had been listed for taxation every year declared uncollectible. (599.)

Objections to the personal-property tax.—Mr. RALSTON submits a report which he prepared for the Washington Board of Trade upon a bill proposed to be introduced in Congress, relative to the assessment and collection of taxes in the District of Columbia. In this report Mr. Ralston sets forth certain objections to taxation of personal property: (1) Such a tax is inquisitorial in its nature. (2) Because of this fact false returns are rendered, and wherever the enforcement of the personal-property tax is attempted truthful men suffer and the unscrupulous gain. (3) Personal taxes are unequal with reference to the ability of businesses to bear them, and therefore force some men out of their occupations and so foster monopoly. (4) A personal tax does not commonly rest on those at whom it is directed. A tax on the stock of a store-keeper is ultimately paid not by him, but by his customers. It is therefore not a tax upon accumulated wealth, but upon the necessities of life, and therefore falls upon the poor in infinitely greater degree than on the rich. In like manner a tax on money loaned is secured by the lender from the borrower, in the shape of commissions or of a higher rate of interest. In this case also the necessitous pay the tax and the wealthy escape. (5) A personal tax is always a double tax. If a man borrows \$1,000 to help in buying a piece of real estate worth \$2,000, and if he pays taxes on the value of the real estate and also on the \$1,000 borrowed, it is evident that he pays taxes on a total valuation of \$3,000, or pays twice on the borrowed \$1,000. But all personal taxation is double taxation in a broader and less obvious sense. Real estate increases in value, according to the opportunity it affords for the possession, preservation, and production of personal property. If we tax both the opportunity for producing, preserving, and enjoying wealth, as represented by real estate, and also the thing preserved or enjoyed, in the form of personal property, we inflict double taxation. (6) Some personal property, as Government bonds, is exempt by law, and this introduces an inequality between some owners of personal property and others. (7) A personal tax is readily evaded. (8) A personal tax interferes with thrift and throttles industry. To tax articles produced is to diminish production, and to diminish production is to lessen comfort and create squalor. (9) The assessor can know little of the personal property he assesses, especially under city conditions. (1034, 1035.)

Mr. Ralston cites a considerable number of official reports condemning existing systems of personal-property taxation as inefficient and unjust. The Controller of the State of New York in 1898 declared in his report that the tax upon personalty

COCXCII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

is "unjust as between individuals, unjust as between communities, and, as experience has shown the world over, it is impossible of even approximately just administration." The commission appointed to inquire into the expediency of revising the tax laws of Massachusetts, in its report issued in October, 1897, states that "everywhere, without exception, the testimony is that this part of the system of the general property tax is unequal, unsuccessful, often demoralizing to tax officers, always irritating to taxpayers." The New Jersey Commission on Taxation, in its report of 1897, declared that "the only ones who now pay honest taxes on personal property are the estates of decedents, widows and orphans, idiots and lunatics." The Ohio Tax Commission reported in 1893 that "the system as it is actually administered results in debauching the moral sense. It is a school of perjury. It sends large amounts of property into hiding. It drives capital in large quantities from the State." (1037, 1038.)

Mr. GEORGE, formerly an assessor, says a banker in his town bought Government bonds previous to the first of May, when an assessment took place, and after the assessor had made his estimate, found it profitable to sell the bonds and loan out the money, sometimes at 10 and 20 per cent, on short-term paper. In Chicago tangible property is practically confiscated, while those who have their investments in some other form escape by not listing their property. Even under the new compulsory law they are refusing to schedule their property. A man does not want to lie if he can escape it by saying nothing at all. (221.)

Mr. BURKE says the farmer is chiefly to blame for the personal-property tax. He always demands it, on the mistaken hypothesis that the business man would escape if personal property were not taxed. (195.)

2. Equalization on the basis of local taxation.—Mr. RALSTON mentions a plan recently proposed in the New York legislature for the equalization of taxation between communities. It is proposed to fix each community's share of the State tax as a percentage of the tax which it raises for local purposes. (1028.)

3. Partial exemption of houses.—In a report prepared for the Washington Board of Trade upon a bill relating to taxation in the District of Columbia, Mr. RALSTON suggests a partial exemption from taxation of houses occupied by their owners. The exemption proposed extends to \$1,000 of assessed value in each case. It is suggested that such a measure would increase the number of home owners by placing a premium upon the purchase of homes and diminishing the annual outlay necessary to maintain them. It would stimulate the construction of more and better houses and increase the employment of labor in building them. The whole community would share in the benefit of this quickening effect. It would tend to the use of larger lots, because men would be better able to afford them, and would so promote the health of the community. The temporary diminution of revenue would probably be speedily offset by the increased production of houses and by the rise of land values due to the larger use of land. (1036, 1037.)

4. Taxation of productive property and occupations—License taxes.—Mr. HAMILTON, Secretary of Agriculture of Pennsylvania, believes that all income-producing property, professions, occupations, and industries, including the franchises of corporations, etc., should be taxed according to net income or profit. The implements of the trade or occupation, carriages for personal use, furniture and other naturally unproductive property the necessary parts of the equipment of a comfortable home should be exempt. A house or building that may be rented should be taxed, being capable of production. The tax on each piece of property should have a direct relation to its income-producing power, and should never exceed the net income. The State can not afford to require an individual to pay a tax greater than the producing power of his property, for anything that impoverishes the citizens is a detriment to the State. Mr. Hamilton would tax vacant lots in accordance with the average annual increase in value, and would apply the same principle to undeveloped mining property and woodland. A part of the income, he says, should be left to the owner as interest, so that he can be induced to keep his money in that kind of property and ultimately make it productive; then the State will get the advantage of the tax. To tax comparatively unproductive property, as a vacant lot, according to the value of the surrounding lots, would be confiscating the property. (359, 360, 363.)

Mr. Hamilton testifies that about 50 years ago Pennsylvania was forested through a breadth of perhaps 100 miles from the Virginia line to the New York line; but to-day there is hardly any timber in all that region, and it is impossible for a man to hold timber land. The tax on timber land will confiscate it in a very few years, and the owners have been obliged to cut the timber and sell it in self-defense. Localities have raised the tax on timber land so that the annual growth would not begin to pay the tax and the interest on the money invested. Quantities of lands have been abandoned and sold at tax sales because the owners could not afford to hold them. If there had been some system by which the owner had been allowed a fair income,

DIGEST:—PROPOSED REFORMS IN TAXATION. ' COOXCIII

a million acres would be to-day in the hands of the owners for the maintenance of a great industry which has nearly left the State. Landowners are coming to the Forestry Commission and wanting it to take lands at from 50 cents to \$1.50 an acre which a few years ago were worth a large amount of money because of the timber on them. (363.)

Mr. Hamilton suggests that reforested lands should be taxed annually on their estimated income-producing power, and that when the timber is finally cut the tax should be levied upon the product, instead of putting a ruinous tax upon the land while the timber is growing. Putting the main tax on the product would defer the cutting of the timber as long as possible, and make it to the advantage of capitalists who wished to invest their money over a long series of years to put it into timber land, with the assurance that it would not be taxed out of existence, but would ultimately pay a revenue. (365.)

Mr. Hamilton is of the opinion that places of religious worship, educational and charitable institutions, and cemeteries and burial lots should be exempted from taxation, a tax upon them being a discouragement of religion, morality, education, or charity. Every man is bound to support good order, and the church is the best policeman in any city; any burden laid upon the church is an additional burden upon the individuals composing it, and it is unfair to increase the burdens of men who are already doing their full duty as citizens and taxpayers, by requiring them to pay a tax upon an object of beneficence. (358, 361, 363.)

Mr. HAMMOND, of South Carolina, suggests the classification of lands and the valuation by classes and the taxation of licenses and franchises. He would also advocate a license tax on cotton planting in proportion to acreage. This would diminish the excess of expenditure in that direction and turn the energies of the community profitably to other pursuits. (828.)

Mr. MILLER thinks the constitution of Ohio should be so amended as to make it legal to impose a license or control the sale of intoxicants. There would be a more responsible class of people in the business, it would be better controlled, and a larger revenue would be received from the business which adds greatly to the burdens of the people. (613.)

Mr. RALSTON declares that trade licenses or occupation taxes infringe the inalienable right of all men to life, liberty, and the pursuit of happiness. They nearly tax out of existence the poor and defenseless, while the rich accept their comparatively small occupation tax as a partial protection against competition. To them the occupation tax is useful in the maintenance of business monopolies. This is in itself a gross perversion of the taxing power. However, the identification of those engaged in certain occupations is sometimes desirable, and a high license tax on certain occupations may be desirable for police reasons. Identification could be secured where necessary by a nominal tax of 25 or 50 cents a year. (1035.)

5. Income, inheritance, and corporation taxes.—Mr. POWERS says the systems of taxation of most of the States need complete remodeling. They were developed at a time when all property was visible; but visible forms of wealth now make up only about one-half of the total, and about one-third of the property of the country escapes taxation. To meet these conditions we must change our methods and adopt various forms of taxation suited to the time—the corporation tax, inheritance tax, and income tax. (184.)

Mr. AGER favors an income tax and both a collateral and a direct inheritance tax, and says that corporations should pay their share. (112.)

Mr. JONES, master of the National Grange, advocates a graded income tax, with the exemption of a reasonable cost of living. The tax should be so adjusted to the general property tax as not to involve a double burden on the same income. Mr. Jones opposes the single tax, and also the inheritance tax, on the ground that if a man has paid taxes fairly during his life it is unjust to take from his children a part of the property he leaves. (36, 37.)

Mr. GEORGE believes that the only way to reach capital successfully is by an income tax. He says it is easy for a man to pay taxes if he gets the money, but it is not easy to pay taxes if he is not earning anything. (221.)

Mr. HALE favors an income tax in the States. He believes in the justice of a graduated income tax, but he would have everyone a taxpayer. He thinks the humblest citizen would have more interest in local and State governments if he paid a small tax. Mr. Hale does not think that any upright business man would be injured by having his income made public. (387, 388.)

Mr. STOCKWELL considers the income tax a just tax, but not sufficient. There should be also a tax on property, and honest returns should be enforced. (900.)

Mr. Stockwell declares that those corporations that yield a return of 12, 20, and 40 per cent ought to be taxed according to ability. It is perfectly legitimate to let their returns be known to the Government which protects them and gives them their

opportunity. Taxation of the giant monopolies according to their ability would not help the prices to the consumer, but would lessen the burden of general taxation. (898, 900.)

Mr. RALSTON, in a report prepared for the Washington Board of Trade with reference to taxation in the District of Columbia, deprecates the levying of any special tax upon corporations, excepting those which enjoy natural or artificial monopolies. If any such special tax is to be levied, he suggests, as one involving the minimum of evil, a tax upon their net earnings. (1035.)

6. A single tax on land values.—Mr. REDDING, director of the Georgia Experiment Station, would substitute the single tax for the present system of taxation, taking all taxes off personal property. (452.)

Mr. BURKE, editor of the *Farmers' Voice*, advocates a single tax on land values, believing that there is no other form of taxation that is equitable and just under all circumstances. No one can own personal property to a very large amount, except in the form of jewelry and small trinkets, unless it is in some way related to land. Stocks and bonds have their basis in land. A merchant would not escape taxation under the system proposed, because he must have a store, the rental on which would go into the public treasury. Taxation, Mr. Burke says, should encourage trade, and not put a fine upon it; the benefit would be diffused through the community, because goods would be sold more cheaply. The hypothesis of the single tax is that society has created land values. It is a form of taxation which is not taxation at all, but simply rental regulated by the law of supply and demand. The fee simple would not be altered and the mode of assessment and collection would not be changed. (195, 196.)

Mr. Burke thinks assessment would be equitable under the single-tax system because the map in the county treasurer's office would show the valuation of each piece of property. He thinks no other scheme of taxation has ever been devised to open taxation to the inspection of all. A published list of taxes would not show anything under the present system because of the improvements on some property; but if there were no buildings involved any discriminations would be apparent. The single tax, he says, would also prevent inequalities between different sections of the State, because there would be a common basis for comparison. (198-200.)

Mr. Burke says the farmers of Illinois do not want the single tax, but thinks they would favor it if they did not have an idea that it would disturb their fee. Under it the farmer would not pay a tithe of the taxes he now pays, and every railroad and every corporation which has the slightest relation to land would pay upon its land values in the same ratio as himself. A farmer would pay only upon original land values. Cook County would pay its fair share. Mr. Burke cites figures to the effect that Cook County has more than one-third of the total real estate values of the State, but only one sixty-third as much as the rest of the State in watches and clocks, one twenty-second as much in carriages and wagons and in money, and one-tenth as much in credits, as shown by the assessed valuation. Personal property is only 13½ per cent of the total valuation in Cook County and 17.7 per cent in the remainder of the State. Mr. Burke says some one must make up for every piece of personal property that escapes taxation. (197, 198.)

Mr. Burke thinks a single-tax law would settle the question of trusts, as well as the question of taxation, by destroying special privileges. (200.)

Mr. RALSTON defines the single tax as

"A system of taxation which calls for the levying of all taxes on the value of land, exclusive of the improvements borne upon the land. When carried to its logical ultimate, it would involve the doing away with all tariff taxes, and with all license taxes, with a possible exception in so far as license taxes are imposed for police reasons; the abolition of all taxes on personal property and of taxes upon the improvements upon land, leaving as the sole subject of taxation the value of land itself, the one thing which is not the direct result of labor, and which is rather the incidental result flowing from the advancement of the community, from the perfection of government, from the educational and other advances incidental to the community, transportation facilities, and any of the elements that would naturally conspire to maintain or increase the value of land."

Mr. Ralston explains that the single tax is entirely different from land nationalization, and does not involve any ownership of land by the state or any change of ownership or management. Mr. Ralston understands that the socialists believe in land nationalization and would have the community own the land and determine the use to which each parcel should be put. The single taxers would leave the land in the possession of its owners and leave them the management of it as exclusively as now. (1019, 1027.)

In the belief of single taxers there has been a constant groping toward the single tax for several hundred years. Mr. Ralston cites several French philosophers of the seventeenth and eighteenth centuries. Turgot, the great French minister, tried to reform the system of French taxation in the line of a single tax. The vested interests of

France were too strong for him and he ultimately lost his power. Later several English writers set forth the general principles which are now grouped under the name of the single tax. The theory has been elaborated most logically and most completely by Mr. Henry George. Mr. George did not claim to be the originator of his system. The ideas which are associated with his name may be found in writings of far earlier date. He assembled and grouped those ideas and clothed them in a style of unsurpassed literary excellence. Mr. George himself refers in the course of his argument to such names as those of Adam Smith, John Stuart Mill, and Herbert Spencer. The present movement toward the single tax may, however, be dated from the publication of Mr. George's *Progress and Poverty* in 1879. Mr. George's campaign for the mayoralty of New York in 1886 gave notoriety to the movement, and it was brought again into prominence by his second campaign for the mayoralty in 1897. (1019, 1020.)

Mr. Ralston mentions several legislative proposals which have looked toward partial or complete adoption of the single tax. About 1891 a subcommittee of the Committee of the House of Representatives on the District of Columbia, headed by Hon. Tom L. Johnson, made an investigation of the system with respect to the advisability of putting it into effect in the District of Columbia. The report of the committee was favorable and was supported with an abundance of tables. When the Wilson bill was before Congress an amendment was introduced providing for the taxation of land values throughout the United States as a supplement to the taxation of imports. The amendment received the votes of such men as Mr. Harter, of Ohio, Mr. Tracy, of Albany, N. Y., and Mr. John De Witt Warner, of New York City. It was of course defeated. At the last session of Congress a bill was introduced for the gradual adoption of the single tax in the District of Columbia. It was referred to the Committee of the House on the District of Columbia, and nothing came of it, though it received the sanction of the labor organizations of the District.

Some 3 years ago an amendment to the constitution of the State of Washington was passed by the legislature and submitted to the people to permit local bodies to adopt the single-tax system, if they should desire, for local purposes. Though not necessarily a single-tax proposition, it was so treated by the people and press of the State. It was defeated, but it received a very heavy vote in the popular election. At the last session of the legislature of Colorado a somewhat similar constitutional amendment was adopted by a vote of about 4 or 5 to 1, which will be submitted to the people in 1902. A similar amendment was discussed in the last session of the legislature of Delaware. It passed the lower house and was defeated in the senate by pure accident, through the momentary absence of one advocate of it, and the negative vote of another, cast under a misunderstanding. Several similar propositions have come near adoption in other States at recent sessions of their legislatures. One was lost in the State of Michigan about 2 years ago by 1 vote in the house, after having passed the senate. (1020, 1021.)

Mr. Ralston declares that the single tax has received the very general sanction of labor organizations throughout the country, and that it is impossible to find any opposition to it among them, unless on the part of individuals who have not studied the question or who are biased by what they consider their more immediate personal interests. A surprisingly large proportion of newspaper men also believe in the single tax. The idea does not yet find support in the editorial columns of the press; but this, the witness believes, is because the editorial columns are largely controlled by the business office, and business interests are not yet sufficiently educated on this subject to realize that their best development will be found in the line of the single tax. (1020, 1021.)

Some 60 years ago the common council of the town of Alton, Ill., passed a resolution providing that all taxes should be levied upon the value of the land, and that improvements and personal property should be exempt. Mr. Ralston's knowledge of the fact is derived from a report of a case in one of the earliest Illinois Reports. The case related to the validity of a tax deed. The constitution of Illinois provided that all property should be taxed, and the question arose whether the town of Alton had violated this provision. The supreme court decided that Alton had no right to make the exemptions it had made. Mr. Ralston remarks as a curious fact that the arguments of the attorneys for the town in this case were substantially the arguments now brought forward by single taxers; namely, that such a system of taxation would prove beneficial to industry, would tend to the building of houses, and might do away with the holding of land out of use, for speculation, to the detriment of the community. Mr. Ralston describes a similar experiment in which he himself was directly interested. The town of Hyattsville, Md., where Mr. Ralston lives, decided in 1892, by vote of the board of commissioners, to exempt improvements from taxation. Personal property was already exempted. Upon the assessment roll of the

CCCKXVI THE INDUSTRIAL COMMISSION:—AGRICULTURE.

town was a column for land values, a column for improvements, and a column for personal property. The only change of system was to strike out the improvement column and the personal property column. The rate of taxation was raised from 15 cents to 25 cents. Taxes were collected under this system for 1 year. The speculators of the town antagonized the movement and appealed to the courts. In the circuit court the town was sustained, but the court of appeals held that the measure was not authorized by the charter of the town and was unconstitutional. Mr. Ralston adds that since that time the single tax has not been attempted in this country, largely and perhaps altogether because of constitutional difficulties. (1022, 1031.)

In New Zealand a considerable proportion of the colonial taxes are levied on the value of lands, exclusive of improvements. A considerable number of towns or local taxing districts have also adopted the single-tax system for local purposes. No town or taxing district in New Zealand, having once made the change, has gone back to the old method. Adjoining towns, seeing the benefit of the new plan, have adopted the single tax by majorities running as high as 8 and 10 to 1. (1022, 1023.)

Mr. Ralston asserts that a tax upon the value of improvements deters the making of improvements. If it is a good thing that improvements be made, we ought to avoid that which in a degree prevents them. One of the most effective ways to diminish the number of dogs is to tax them. In France there is a tax on windows and doors. It diminishes the use of windows and doors, to the detriment of health. England had the same experience with a window tax, and also with a tax on fireplaces; the number of windows and the number of fireplaces were diminished. The tax on houses has an effect exactly similar to that of a tax on dogs or on windows. It compels people to live in poorer houses, because in paying their rent they have to pay the tax. It limits the employment of labor in producing houses. (1023.)

Mr. Ralston discusses the question of the taxation of improvements upon land from the point of view of the benefit derived from the expenditure of taxes. If a street in front of a house is improved, the value of the house is not increased or maintained by it. The value of the house is added to by things that the owner does—painting or building an addition. The town, by improving the streets, adds value to something, but not to the house. The whole benefit of the street improvement is added to the value of the land. The same is true of sidewalks, sewers, and water systems. The value of the land is increased by such improvements, but the value of the house itself remains the same. It is said that the house ought to be taxed because the taxes pay for protection from fire and from violence; but the fire department and the police, however efficient, do not in the least increase the value of the house. They do increase the value of the land. If a house in one locality is better protected from fire or from thieves than a house in another, the land that that house stands on will have a higher value than the land that the other house stands on; but the houses themselves, if they are similar, will be of equal value. For a tax upon a piece of land, whether it is expended in street improvements or in police or fire protection, the owner of the land gets a money return; but for a tax upon his house he gets no return. Somebody, however, does get it. Suppose that beside the house there is a vacant lot; the value of that vacant lot is increased just as much by the street improvements and by the protection against thieves and against fire as the value of the lot on which the house stands. The owner of the vacant lot gets the return, not only for the tax which he pays on his lot, but also for a part of the tax which his neighbor pays on his house. The single taxer holds that in this injustice lies the secret of the maladjustment of society. So long as taxes are laid on the property of one man and expended for the benefit of another man, a proper adjustment of industrial conditions is impossible. It is necessary to readjust the system of taxation upon the clear, logical, and just basis of giving a man just what he pays for, and not taking money from one man and giving it to another. (1022, 1023.)

Mr. Ralston points out that great quantities of land that ought to be used are held idle, in order that their owners may make a profit by the rise in value. The people in the cities are crowded together in narrow quarters, and the workmen who would be glad to build larger and better houses for them are deprived of employment. If the tax on houses were abolished and the tax on vacant lands were increased, it would no longer be profitable to hold land idle for speculative purposes. When the adoption of the single tax in Hyattsville, Md., was proposed, some of the landholders said, "If we have the single tax the tax on land will be so high that no poor man can buy a lot." But when the single tax was adopted they said, "We can not afford to pay these taxes, and we shall have to sell at any price if we do not get rid of the single tax." The effect of the single tax would be to increase the amount of land available for use, to lower the selling price of it and encourage building, to increase the employment of labor, and to give the people better conditions. (1025, 1026.)

Mr. Ralston declares that in the opinion of the upholders of the single tax the recurrence of hard times is due to the vicious system of holding land for speculation, which is connected with a vicious system of taxation, and until this is corrected hard times will constantly recur. The inheritance law of France is believed by single taxers to have contributed to the comparative exemption of France from industrial depressions and to its rapid recovery from the ravages of war. France does not allow a man to will away more than a certain amount of land from his children. The system is not theoretically the best, because it divides land into too small holdings and makes it impossible to work land in the most economical way. Yet in a large degree it has proved the salvation of France. (1026, 1029.)

Mr. Ralston says that in the opinion of single taxers one man has as good a natural right as another to be upon the earth and to enjoy the blessings of life, liberty, and the pursuit of happiness. If one man owns the land upon which others have to live, he possesses not only his own right to life, liberty, and the pursuit of happiness, but theirs too. They have to pay him for the privilege of existence. Men are not equally free when one has to pay tribute to another to get at the earth upon which all must live. Assuming the equal right of all men to make use of the earth, no measure is necessary to secure this right except the payment into a common fund, to be disbursed for the common benefit, of the special value which accrues to the owners of land merely as owners. If 20 men were common owners of a horse and the yearly value of the use of the horse were \$20, the rights of all would be secure if one man used the horse and paid \$20 into a common fund, to be disbursed to all the stockholders. So if the net rental value of the land of the United States is \$1,000,000,000 a year, if the owners of land pay that billion dollars into the common fund and it is disbursed for the benefit of the whole community, the equal rights of everyone to the land upon which all work and live will be recognized, and the extremes of poverty and wealth which now exist because certain persons get the whole benefit of the value of land will disappear. (1026.)

Mr. Ralston explains that under the single-tax system the taxes for the General Government, as well as for the State and the localities, would be collected just as the State and local taxes are collected now. No new system would be necessary. It is impossible to say with accuracy what proportion the share of United States taxes which would fall to a particular State, together with all the State and local taxes, would bear to the rental value of land. Mr. Shearman, in his work on Natural Taxation, shows satisfactorily, in Mr. Ralston's judgment, that the present rental value of land, exclusive of improvements, is more than enough to meet all local and general taxes. (1026, 1027.)

Mr. Ralston does not admit that private ownership of land has been instrumental in bringing us to our high position in civilization and wealth. He thinks it has been a deterrent, in that it has enabled land to be held out of use. This withholding of land has thrown people out of work, has prevented the orderly development of cities, and has amassed great wealth in the hands of some people and held others in poverty. (1028.)

To the question whether a small manufacturer might not be ejected from his place of business by a rich and powerful rival, under the single-tax system, by the process of outbidding him for the use of the land on which his factory stands, Mr. Ralston replies that such a bid could not be accepted by the assessor nor supported by the community. The tax to be levied is determined by what the community generally is willing to pay for the use of the land. It would not under any circumstances be determined by the extraordinary offers of an individual. Property does not rise in value in an extraordinary degree in a particular square and not in a neighboring square similarly situated. (1029.)

Mr. Ralston goes on to say that the tax on land would increase with the value of land just as it does now, though in a greater degree. It happens to-day that improvements become valueless because of changes in the surroundings of the land. Improvements which were made 20 or 30 years ago at great expense may now be entirely disregarded in selling the land in some cases, because they are no longer suitable for the situation; they have become valueless. That might happen under the single tax to the disadvantage of owners, but it happens to-day. (1028.)

Mr. Ralston expresses the opinion that taxes can be shifted only through some change that they make in the value of the thing taxed. The value of a thing is increased either by increasing the demand or by diminishing the supply. Taxing a hat discourages the making of hats and diminishes the supply. A man will not go on making hats unless he can get the tax out of the consumer. Taxing a house diminishes the supply of houses, because people will wait before building houses until they can get the tax out of the tenants. Diminishing the supply increases the value.

CCCXCVIII THE INDUSTRIAL COMMISSION:—AGRICULTURE.

This increase of value which the tenant has to pay to the owner constitutes the shifting of the tax. But the tax upon land does not in any way diminish the supply of land. It rather increases the available supply, by opening up for use land which would otherwise be held for speculation. It diminishes rather than increases the value of land. It does not introduce any condition which enables the owner to get more rent from the tenant, or, in other words, to shift the tax upon him. (1032, 1033.)

Mr. Ralston says that while a great manufacturing concern like the Brooks Locomotive Works would perhaps be greatly benefited, its taxes greatly lightened, by the adoption of the single-tax system, almost all the home owners in the town would also be benefited. No one would suffer except the man who was holding his land out of use or who had improved it inadequately. In support of this statement Mr. Ralston cites the actual experience of his town of Hyattsville. When this town adopted the single tax its total assessment was \$600,000. The lands were valued at about \$400,000, improvements at \$200,000. When the land value only was taken as a basis the \$200,000 of improvements was stricken off the rolls, and the tax rate was raised from 15 cents to 25 cents a hundred. Practically every householder in the town paid less tax than before, yet the town raised slightly more revenue. Vacant land was assessed just as high as improved land similarly situated, and the whole amount of the tax which was taken off the householders was put upon the speculators. (1030, 1031.)

Mr. Ralston declares that the tax on land values is not a tax on labor but on opportunity. Labor does not create land values. It is the people as a whole that create land values, and the more intelligent they are, the more they advance in every respect, the higher the land values go. (1031.)

Mr. Ralston admits that if a man owns a lot and is unable to improve it as surrounding lots are improved the tax might be raised under the single-tax system until he should be unable to pay it. He admits that this might amount to confiscation. The question arises, he says, whether that sort of confiscation is right. If the owner created the land value, or if he can show any natural right to the land, the confiscation is wrong; but if the value of the land was created by the whole community, as it is, and if the owner did not create the land or bring it into existence, the confiscation is right. The man who is simply a landholder, doing nothing with the land, whether from poverty or from any other cause, while his neighbors are building up the town around him, is doing a positive injury to the community. If he could show as clear a title to the land as to his hat or his house, which he has made, no doubt he should be permitted to keep it in spite of the injury he does; but he can not. The hat or the house was made by his individual labor, or by the individual labor of men who have conveyed it to him. The value of the land is created by the community; and the whole community, being the creator, should have the benefit of the value. (1031, 1032.)

Mr. Ralston admits that farmers in general are prejudiced against the single tax, and suppose that it would lay a special burden upon them. He declares that this is a mistake. The farmer thinks of himself as a great landowner; in fact, he is not. He is a great land user. Land ownership, measured by value, is predominantly in the cities. The farmer pays a heavy tax on goods coming through the custom-house; he pays a heavy tax on his personal property, out of all proportion to the personal tax paid by men in cities; he pays a tax upon his house, his barn, his outbuildings, his fencing, his fruit trees, and upon everything that he does to give value to his premises. In the case of the average farm the value of improvements is vastly greater than the value of the naked land. Mr. Ralston cites an instance in Prince George County, Md., in which a tract of unimproved land about 25 miles from Washington sold for \$1.10 an acre, and a neighboring piece of land, equally distant from the railroad, improved with fences, stables, barns, and a fair, average farmhouse, sold for \$20 an acre. Mr. Ralston admits that this is an extreme instance, but it differs from average cases only in degree. Mr. Ralston refers to an investigation made about 5 years ago by Mr. Robinson, a statistician of the Department of Agriculture, covering 6 or 8 counties in New York State and perhaps some in Pennsylvania. The conclusion was that the farmer would be largely the gainer by the adoption of the single tax. Mr. Schilling, of the Bureau of Labor Statistics of Illinois, in a report of some 5 or 6 years ago, pointed out the fact that the value of a single acre of land in the city of Chicago was greater than the value of some whole counties in Illinois—land, improvements, personal property, and all. There are lots on F street in Washington, says Mr. Ralston, of perhaps 2,000 square feet, which are worth as much as 50 farms in Prince George County, Md., with all their improvements. (1024, 1025.)

TESTIMONY.

INDUSTRIAL COMMISSION.

AGRICULTURE AND AGRICULTURAL LABOR.

TOPICAL PLAN OF INQUIRY OF SUBCOMMISSION ON AGRICULTURE AND AGRICULTURAL LABOR.

[The term agriculturist as herein used includes farmers, planters, dairymen, stockmen, nurserymen, gardeners, fruit growers, and all others engaged in agricultural pursuits.]

PART I.—LABOR EMPLOYED.

CONDITION OF LABOR.

1. Increase or decrease in number employed in agricultural labor in the several States during the past 50 years.
2. Comparative condition of those so engaged.
3. Effect of improved machinery on labor.
4. Causes of irregularity of employment.
5. Transient labor in busy seasons.
6. Hours of labor in different agricultural pursuits.
7. Average number of days employed in the year.
8. Tendency of agricultural labor to seek other employment; causes and remedies.

WAGES AND METHODS OF PAYMENT.

9. Daily, weekly, monthly, or yearly payment.
10. Maximum wages; minimum; average, in different branches; in different States and sections.
11. Cash payment, store orders, payment in kind.
12. Tenant houses and tenant-house allowances.

CROP-SHARING, PARTNERSHIP, TENANCY.

13. Practicability and present status of these methods.
14. Loans to tenants, liens on growing or prospective crops; extent of; effect of.

IMMIGRATION AND EDUCATION.

15. Nationality and character of foreign immigrants.
16. Percentage of literacy compared with American agriculturists.
17. Tendency to colonize—to preserve foreign customs and languages.
18. Effect of such immigration upon American agriculture.
19. Suggestions as to regulation of immigration.
20. Colored labor, extent of.
21. School age of children in the different States.
22. Sufficiency of public-school facilities; per cent enrolled.
23. Adaptation of public-school curriculum to the needs of the agricultural people.
24. Technical education.

PART II.—CAPITAL EMPLOYED.

COMPARATIVE EARNINGS OF CAPITAL INVESTED IN AGRICULTURE.

25. Total capital employed in agricultural pursuits.
26. Earnings of capital compared with 40 years ago.
27. Earnings of capital compared with other lines of business—banking, manufacturing, railroading, mercantile, etc.

COMPARATIVE EARNINGS OF CAPITAL INVESTED IN AGRICULTURE—Continued.

28. Taxation of agricultural property. (a) Character, extent, and effects in the different States. (b) Suggestions for modification and unification of tax methods; State and local.

29. Migration of agriculturists from localities; causes and extent of.

THE PRESENT CONDITION OF AGRICULTURISTS.

30. Decline in prices of agricultural products.

31. Decline in money value of agricultural lands in the older States; causes and extent of.

32. Decline in productive condition of soil in said States; causes and remedies.

33. Increase in acreage under cultivation.

34. Its effect on production, on prices, on profits, on wages, on employment.

35. "Bonanza farming." Its effect on production, wages, prices.

36. Organizations of agriculturists; causes inducing; objects sought; results secured; rules governing.

ANNUAL PRODUCTION.

37. Present production in relation to consumption and existing markets.

38. Overproduction in certain lines; underproduction in other lines; causes and remedies.

39. Diversification of agricultural industries.

40. Effect of improved agricultural machinery on production and prices.

41. Extension of foreign markets; possibilities and methods.

COST OF PRODUCTION AND TRANSPORTATION.

42. Cost of production, including interest on capital, cost of labor, and other charges.

43. Increase or decrease in transportation rates during the past fifty years.

44. Good roads; effect on cost of local transportation.

LOCAL MARKETS AS TO PRICES.

45. Combinations to control prices.

46. Effect of so-called "grain and cotton gambling."

PART III.—REMEDIAL LEGISLATION.

AS TO EXISTING FEDERAL AND STATE LAWS TOUCHING AGRICULTURAL INDUSTRIES.

47. Legal regulation of trusts, combinations, and other forms of monopoly.

48. Operation of existing antitrust laws; interstate commerce laws; oleomargarine laws; suggestions for their modification or extension.

49. Operation of existing pure-food laws; objects sought; results secured; advisability of Federal legislation thereon.

50. Operation of existing Federal and State laws to prevent the spread of disease among domestic animals; among plants; suggestions for the modification or extension of said laws.

WASHINGTON, D. C., March 13, 1899.

TESTIMONY OF HON. JOSEPH H. BRIGHAM,

Assistant Secretary United States Department of Agriculture.

The commission met at 11.30 a. m., March 13, 1899, Mr. Farquhar presiding.

Assistant Secretary Joseph H. Brigham, of the Department of Agriculture, testified. (The syllabus on agriculture was followed in the examination of the witness.)

Q. (By Mr. FARQUHAR). What has been your connection with agricultural matters?—A. I have been connected since 1873 with the grange, or the Order of the Patrons of Husbandry. I served 10 years as master of the State Grange of Ohio, and was 9 years master of the National Grange. I was also for some years a member of the State Board of Agriculture of Ohio. During that time I have visited nearly every State in the Union and came constantly in close touch with the farmers of the different sections of the country, which has given me, of course, some opportunity to understand the conditions in the different sections. I do not pretend to be an expert or to know it all, but I have had those opportunities.

Q. Are you a farmer?—A. Yes; I came off my farm when I moved here.

Q. (By Mr. A. L. HARRIS.) What has been the increase in the locality in which you live in the number of laborers employed upon the farm?—A. I think, among the farmers where I am best acquainted, the labor that is employed the year round, the regular employees, are about the same in number—that is, there has not been much decrease; but in hiring transient labor there has been quite a decrease, in my judgment.

Q. What is the condition of those so employed compared with former years?—A. I think that farm laborers have a very much better time than they did 50 years ago. I know that you could hire the best of help on farms then in Ohio, on the Western Reserve, for from \$10 to \$12 a month, and very often they would work from daylight to dark.

Q. What part of Ohio do you live in?—A. I live now in northwestern Ohio; I was born on the Western Reserve, in Medina County. I speak of conditions 50 years ago in Medina County. I was about 10 years of age then, but I know about what they got at that time.

Q. During the time you were master of the National Grange and traveling through the United States in the interest of the grange, did you have an opportunity to observe the condition of the hired labor from time to time?—A. Yes; I had a good opportunity to do so.

Q. What is your opinion of the condition of the hired labor upon the farm of late years?—A. I think he has a very decided advantage over the farmer himself. He has pretty good wages, and the work is not ordinarily quite as heavy, because of the use of machinery, as it was years ago, and is done with much less muscular effort, and the man who boards in the family lives just as the family does, eats at the same table, and they have many advantages that they did not formerly have. It is quite customary for the farm hand to keep a horse and buggy. They have much better times and more conveniences than they did when I was working on the farm for \$12 a month.

Q. So far as labor is concerned, has the small farmer, as a rule, much advantage over the hired man?—A. Not any. When the prices are low he is at a disadvantage, because the wages do not fluctuate as the prices of agricultural products fluctuate. There has been a gradual increase in the pay of the farm laborer from what it was when I was a young man. The hours of labor have been greatly reduced. Occasionally there is a man that gets his help out at 5 o'clock in the morning, but they are very few. I remember when I was out milking cows at 4 o'clock in the morning, and when I got through at night it was dark. They worked more hours; swinging a scythe and cradle was hard, muscular work. They do not do it now. They ride a sulky plow, and a great many other machines that lighten labor, and the farm hand has a better life, better pay, etc., than years ago, when I was a young man.

Q. What has been the effect of improved agricultural machinery on the price of labor?—A. I do not think it has decreased the price of labor. It has decreased the employment of labor in harvesting and haying time a little, but it has not decreased the price. The price has been maintained, and in my judgment it has rather increased. In New England they do not expect to hire a man for less than \$1.25 a day, and they give him his dinner during the busy season.

Q. Compared with 30 or 40 years ago, does the hired man on the farm do as hard work, the same drudgery, now as then?—A. There has been a great improvement in that respect; there are some classes of hard work yet, pitching manure, and some ditching. The latter is usually done by men employed especially for that work.

Q. As a rule, where you have ditching or any extremely hard work, do you generally engage men who follow that business?—A. In ditching, they do; when a man is hired as a farm hand he is expected to do whatever there is to be done. The ditching is not very much, except in the low, wet lands. Of course a hired man is expected to do some ditching if not otherwise engaged; he is expected to help; but we always have experts come to do that kind of work.

Q. What are the causes of irregular employment on the farm?—A. The haying used to last, you know, for several months—several weeks at least; now the good farmer wants to do his haying all up and get it out of the way before harvest time, and then his wheat and oat harvest is not expected to last more than 4 or 5 days; in a few days he can do more now with two men than he could do with several hands in several days when I was working on the farm.

Q. Where do you procure transient labor in busy seasons now?—A. It is a very difficult matter to procure it at all. You have to make arrangements some time ahead in order to be sure, and have to pay pretty good prices to get it.

Q. Do you go to the villages or cities for the help?—A. Yes; we go to the villages, but we do not go to the cities very often. I do not live near enough to the

cities to get labor from them. They will come out and help us thrash, if we pay them pretty good wages; they say they get good food; they like to get together in groups of men. For very heavy work, like corn cutting, it is very hard to get men.

Q. Do you get any assistance in your part of the country from the Canadian labor?—A. Not very much, if any; not where I live. In Michigan they get some, but very little in our part of the country.

Q. Do the railroads extend any facilities to the agriculturists in bringing labor from distances, if desired?—A. No; not that I know of. I never knew them to extend any help of that kind.

Q. Please state the hours of labor upon the farm in different seasons and in different agricultural industries.—A. The situation varies somewhat. In the South they put in more hours than in the North—colored laborers put in more hours. When I was a young man, as I told you, we put in the time from about 4 or 5 o'clock in the morning until about 8 o'clock at night. Of course there were the meal hours, and an hour at noon to take out of that, but we started early and worked very late. Since the war there has been a change in that respect, at least the hours have been greatly reduced, until 10 hours a day is considered good time to put in on the farm. If a man works a team he is expected to take care of his team before that time, and to be ready to be in the field at about 7 o'clock; they take an hour for noon and close generally at about 6 o'clock; of course they have to put up their team. Some farmers let them stop work at 5 o'clock, so they can put up their horses for the night and give them a good currying. They do not get farm labor, ordinarily, for more than 10 hours a day during the busy season, and in the winter a little less than that—about 8 or 9 hours.

Q. (By Mr. RATCHFORD.) Is the reduction in the hours of farm labor due to new machinery or to organizations among the farm hands?—A. There is no organization that I know of among the farm laborers. It is becoming a custom among the farmers generally, I think; they feel they will get as much and better work out of a day of 10 hours than if they undertake to put in too many hours. The man with his team gets into the field at 7 o'clock and works until noon, gets his dinner, and works until about 6 o'clock; then they don't feel like wooden men, as a man will if he does not get sleep enough.

Q. Has it been your experience that a greater and better amount of work is performed in shorter hours?—A. I think 10 hours' good work on a farm is about the limit of what a farmer could expect or would be benefited by getting. I think more hours of labor in a day than that, ordinarily, would be of no advantage to the farmer. I think the man feels better if not worked too late.

Q. (By Mr. FARQUHAR.) Do many agricultural laborers belong to organizations in which they undertake to regulate the hours of labor?—A. No, sir. Of course farmers usually work themselves; they go to the field, take hold and labor; they are on very good terms with their help. Very many of these laborers are members of the farmers' organization.

Q. Are your organizations open to employer and employee, to male and female?—A. Yes, both. Some of our very best members in these organizations are the men and women that work for the employer on the farm.

Q. (By A. L. HARRIS.) Please state the social relations that exist as a rule between hired labor on the farm and the farmer himself.—A. It varies somewhat in different sections of the country. In the North the hired man is usually a member of the family; some farmers prefer to hire a married man, and build him a house so that he can board himself. It relieves the farmer's wife and family of some labor. There are times, always, when members of a family like to be by themselves, and prefer not to have anyone live in the same house with them. A majority of the unmarried laborers are employed by the month or year and board with the family.

Q. (By Mr. FARQUHAR.) How permanent is farm labor?—A. I think that the farmers in the real farming sections of the country, where they make a business of farming—they employ help most of the year, as much now as they ever did. I think the only reduction that has come in that respect is in the transient labor. Many farmers with only 80 or 100 acres like to get along with only one man for permanent help.

Q. What is about the average time men work for the same farmer?—A. A decent sort of farmer (there are some farmers who are not as good as they might be, though they average with other people), when he gets a good man, does not like, ordinarily, to make a change. He will do everything that is reasonable to keep the same help for years. When a man has worked a good while for a farmer, he is very liable to get to a point where he almost owns the farm, and then it is sometimes necessary to change. There is a little of that in human nature. If they get a poor hand they change as soon as possible.

Q. (By Mr. A. L. HARRIS.) How long, as a rule, does an ordinary farm hand who is economical and industrious remain a farm hand?—A. Some of them work a good while. Some of them will save their money and put it on interest; wait until they get a snug little sum and then start for themselves. Others do not wait so long. They go out and rent a farm, thinking they can make a little more than working by the month or year and be their own boss. I knew a young man that started on a farm right after the war. He worked for me 2, 3, or 4 years, and then he bought a farm for himself. He now has nice buildings and a nice farm—one of the best in the neighborhood. I know of several instances of that kind.

Q. (By Mr. CONGER.) Are farm hands, as a rule, generally young men whose ambition is to become proprietors, and who, as a rule, in later life do become owners of farms and work for themselves?—A. A great many of them do; the industrious, saving men do. It depends whether they save or not. A good many men who are good workers do not save money; they spend it as fast as they get it. Men on the farm frequently save more than they do in ordinary walks of life. Industrious, economical men in course of time have farms for themselves.

Q. I had the impression that the average age of the farm hand would be less than workmen in manufactories. For instance, in manufacturing concerns men often continue as employees all their lives, whereas my observation is that a farm hand most frequently becomes a farmer himself in later life.—A. I think a larger proportion of the farm help do that than perhaps other help. There are a great many men who start in on the farm and are good workers and continue as farm hands all their life. They get married and lay up their money as fast as they get it. Late years they have really found, I think—those most observing—that it is better for them to work for a farmer for wages than for themselves. The low prices in products, etc., lead them to this belief.

Q. (By Mr. FARQUHAR.) Does your farm help in Ohio now usually remain there?—A. I think so; I do not think they migrate now; they used to go; they would strike out for Michigan, Indiana, and Iowa, start in, and grow up with the country; they do so very seldom now.

Q. Do you think there are more inducements to remain in Ohio now than there were 35, 40, or 45 years ago, when men went West to take up 160 acres of land?—A. They can not get the 160 acres now.

Q. Are there no inducements to go West now?—A. No; they do not have the Western fever now; they are pretty apt to stay. They sometimes shift about, go from the farm to the railroad, or go to work at something else; there are very few of them, from my observation, that go West now, compared with former times.

Q. (By Mr. RATCHFORD.) In certain seasons of the year is the demand for farm hands greater than at others?—A. Yes.

Q. Are farm hands, during the dull seasons, obliged to seek other avenues of employment, and do they go to the cities and into the mines, etc., during the winter months?—A. A great many young men seek employment in the cities, where there is more company. A man does not like to work by himself; he likes to have associations with others.

Q. But are men obliged to do this as a means of securing employment during the dull seasons of the year?—A. I do not think they go because they are obliged to, but because they like employment in the city, and to have the company of other men, which they can not have on the farm. My experience for years is that it is a difficult matter for us to get the best help to stay on the farm. Transient help in our country is scarce. If a man becomes a day laborer, he finds the demand for his work is greater than he is able to fill, most of the time.

Q. (By Mr. A. L. HARRIS.) Is he master of the situation?—A. Yes.

Q. What is the average number of days of an employee on the farm during the year?—A. A good farmer who has a farm of 160 acres, or even 100 acres, wants help 365 days in the year—that is, every day. A good farmer never gets out of work for his help.

Q. (By Mr. CONGER.) Does he usually use as much help in the winter as in the summer?—A. A man is expected to help take care of the stock in the winter; and there is plenty of work to keep him busy.

Q. (By Mr. A. L. HARRIS.) Is there a general tendency on the part of farm labor to seek other employment; and if so, what is the cause?—A. I think there is quite a tendency on the part of farm labor, bright, intelligent young men, to look for employment elsewhere; they think there is less danger of being lost sight of if they can get into some other kind of employment, and the tendency is to get away from the farm.

Q. As a rule, who does the work on the small farms?—A. On a farm of 40, 60, or 80 acres, if the farmer is an able-bodied young man, he does most of the work himself; that is my observation.

Q. How about his sons?—A. They grow up and work on the farm at home for a while, then, if they desire to remain farmers, they will remain as long as there is plenty of work to do. If there is not enough to occupy them, they go out and seek employment elsewhere.

Q. Is there a tendency on the part of the farm boys when they get a very fair education to get a little restless on the farm?—A. Yes; they want to be doctors, lawyers, merchants—almost anything other than farmers. The farmers are a little to blame for that; they are always talking about hard times; they magnify this matter sometimes. There have been hard times, and a farmer does not always really appreciate good times when they come. A good many farmers do not make any allowances for what they have in the way of good living and the privileges they have on the farm. They figure that what they make on the farm is what they really save after all the matters of living, etc., have been taken out. They do not appreciate the cost of these things if they had to buy them.

Q. You touched upon the remedy that would make the farm more attractive. I wish you would go a little further into that.—A. It is the purpose of our organization to make farm life attractive and give the farmer's family the best social opportunities that are to be afforded anywhere; to stimulate investigation and thought; to let the boys and girls on the farm take up in their associations literary work and learn to discuss all questions of public interest. There is no business in the world that requires more general intelligence than that of farming. Professional work, merchandising, or mechanical work does not compare in breadth with farm work. A farmer has to be a merchant and mechanic, and should know something of law and medicine as well as farming. It is quite necessary to have method and system in his work, and what we are aiming to do is to get the bright young man to know that there is plenty of room on the farm for the exercise of his ability, and there has been a remarkable improvement among the farmers where this work is going on. College graduates are staying on the farm.

Q. (By Mr. FARQUHAR.) Do you have what you call literary circles in your grange and other farm organizations?—A. Many granges meet once a week and have a nice programme—singing, music, recitations, essays, and discussions—a right good literary society. It is also a fraternal body, and one of the main features is to shake hands and be just as happy as you can; to look on the bright side always.

Q. How many miles does one of these granges take in?—A. We like to have organizations in every township of 5 or 7 miles square. In the little State of New Hampshire there are 244 granges. You see how they are fixed there. In many of the larger agricultural States they are not so thickly located. But it is the purpose and work of this organization to help the farmer in any way it can—financially, socially, intellectually, and in deciding great political questions.

Q. (By Mr. A. L. HARRIS.) What, as a rule, is the method of payment on the farm—by the day, month, or year, or is it changed to suit the occasion?—A. It changes to suit the occasion. The farmers pay cash; they do not pay in store orders or ask help to take anything in lieu of money. If the man works by the day, and wants his money at night, it is usually ready for him. If he works by the month, and wants it once a week, Saturday night, they calculate to have it for him. Most of the farmers employing labor make that arrangement. Very few ask for money and do not get it. There are sections, perhaps, where this would not be true. I am speaking of conditions such as we have in Ohio, Indiana, Michigan, and through that country. I do not know so much about conditions of labor in the South.

Q. What is the maximum wage earned upon the farm for a good farm hand in your part of the State?—A. A good farm hand, if he works by the month, will get from \$18 to \$20 and his board and washing. If he works by the year, and gets his board and washing, they will pay him perhaps \$180 to \$200 for the year. A good many farmers let a man board himself.

Q. What is the minimum wage?—A. I think for monthly wages, perhaps the minimum for the 8 months of the year is \$15 and board and washing. If he works by the day, \$1 a day. Sometimes a man will board himself if he has a family nearby, and will then work for \$1 to \$1.25.

Q. What will be the average for the ordinary farm hand?—A. \$16 or \$17, perhaps.

Q. (By Mr. FARQUHAR.) Do wages of farm hands rise with higher market prices of farm products, or fall with shrunken prices of produce?—A. Wages on the farm do not fluctuate with the price of farm products, as a rule, but if products have been low for a series of years, farmers will hire less help or ask the help to accept lower wages as a condition of employment.

Q. (By Mr. A. L. HARRIS.) You spoke of farmers having tenement houses and hiring married men. How far does that practice prevail in your section?—A. There are quite a number of farmers that hire that way. They build tenement houses and the farm hand moves into the house with his family. He works all the year ordinarily. They give him, generally, his house, and he has his garden patch and a cow and a pig, and a few chickens. Sometimes they keep a horse. I have hired several men that way, and their pay ranges from \$210 to \$240 a year, and give them the house and their wood and the other things named. Occasionally a man did not care to milk a cow, and he would not keep one, but would get his milk at the house.

Q. What, as a rule, is the condition of those tenement houses?—A. Usually not large houses, but comfortable, and better than we used to live in when we were young; frame houses, most of them. Very often the tenement house is the house moved off the old site, when a farmer builds a new one, and some of them cost \$700 or \$800, and some of them \$300. A good farmer generally thinks it best to give the help a pretty fair house to live in—they feel better about it.

Q. Does the tenant furnish his house?—A. Yes.

Q. (By Mr. RATCHFORD.) Are there other advantages afforded the tenant, such as cheaper produce, flour, fruit, etc.?—A. The fruit on the farm is usually free; the tenants help themselves; they have all they want during the season when fruit is plenty. If they put up some winter fruit that is salable in the market, they pay the market price for it. Very frequently a man will go to the grocery and buy flour. Of course, the farmer would let him have wheat at the market price. I had a man who would frequently buy up 20 or 25 bushels of wheat and draw flour when he wanted it.

Q. (By Mr. A. L. HARRIS.) Have you any crop sharing in your part of the country?—A. A good deal.

Q. I wish you would state the methods of crop sharing and their effect upon the farmer.—A. I think the average farmer favors renting his land and getting a share out of it rather than paying money. The average man will take a little more interest in the work—a little better care of the crop and the stock, if he is taking care of his own stock, and the tendency is in that direction. I think the help on the farm will very largely, in the future, receive a share of the crop for their pay rather than be hired outright for money. There are several reasons why I think so. There are occasionally men who don't care whether they make money farming or not. They hire for the sake of bossing; they want the work done just as they want it whether it pays or not.

Q. Who furnishes the stock and equipments of the farm when it is run on shares?—A. Customs vary. Occasionally a man furnishes everything. He puts the man on the farm and says, "I will furnish seed, team, and tools, and you do the work for a certain share of the crop." Another plan is for the tenant to furnish half of everything. Occasionally a tenant furnishes his own team and tools and they divide the crop equally. The team is kept on the farm. He has usually, then, a couple of cows for his own use. The owner of the farm has no share of their product. That is one plan I have worked upon. I have two plans. I go into partnership with my man. He furnishes half and I furnish half of everything on the farm. He does all the work, and when anything is sold we divide the money. When he is taking care of his hogs he is taking care of my hogs. We divide up at the end of the year, or when anything is sold. I have another man who has no equipment. I furnish everything, let him do the work, and then we divide a little differently.

Q. How do those two methods compare with cash rent?—A. I would not rent for cash at all.

Q. What effect does it have?—A. It ruins the farm in a few years. Of course, a man might draw a contract so strong and enforce it so rigidly as to maintain the fertility of his land, but ordinarily it could not be done. But when you rent on shares the tenant will usually take good care of the farm; he has to sow the clover seed, to haul out the manure, and if he does not keep the farm up you do not keep him; he loses his job.

Q. Have you any system of loaning money to your tenant?—A. We do not do that. If a man wants to take half interest, and we think he is all right, we will give him a chance to pay for his half in installments, but we do not usually loan money.

Q. Do you regard it as not being a good practice?—A. That is not a good practice in our country; of course, I have done that occasionally.

Q. (By Mr. CONGER.) When the tenant only furnishes the labor what share does he receive?—A. About a third, generally.

Q. Are those shares, the half and the third to the tenant, fixed by custom, or do

they vary?—A. That is about the way it goes with us. In some sections, however, the tenant is required to furnish almost everything—that is, his team and tools—and take half the crop. It depends on the soil a good deal. If the land is very productive the tenant can furnish a little more. Generally the tenant has good pasture land for the stock that he keeps. Almost every man has some different features in his plan.

Q. (By Mr. FARQUHAR.) Do you think the man who works the farm has an advantage when the owner furnishes everything?—A. I think the plan is ordinarily a little better than when he has to furnish half of everything.

Q. (By Mr. RATCHFORD.) Do you believe that a high productiveness of soil increases the ability of the tenant to pay the landlord a proportionately higher share?—A. Yes. If the soil is good, his crops will be better.

Q. Do you believe the landlord is entitled to a proportionately higher share from the tenant where the soil is rich than where it is not rich?—A. If he furnishes him with better land, his capital is more. He offsets his labor against the capital of the landlord in the soil, stock, and tools, all of which have cost somebody a good deal of labor. If a farm will produce 25 bushels of wheat to the acre, and the farm beside it will produce only 20 bushels to the acre, the land that produces 20 bushels is not worth near as much to the renter as that which produces 25 bushels; in other words, it will cost just as much labor to raise 20 bushels as 25. The 5 bushels is all profit. The landlord gets part of it. I know some men who have worked new ground, where the labor was greater and the crop not quite so large, who received two-fifths instead of one-third. The condition of the soil, the markets, the location of the farm, have very much to do with it.

Q. (By Mr. KENNEDY.) When a man gets one-third, as you have mentioned, is that as much as the owner could allow, after the tenant was permitted to raise potatoes and other vegetables?—A. Yes; he also has his garden produce. The landlord hardly ever looks after that. If he lives on the farm, he has all the fruit he wants usually during the growing season. Of course when the winter apples are gathered they are divided, but I never knew a farmer to make any account of the fruit used during the summer season; that is, the apples, etc. If he raises the ordinary garden stuff, enough for the family, the landlord hardly ever pays any attention to that or expects to get any share of it. However, some do. A man who lives in town sometimes makes an arrangement to have some share of that; and if he does, he furnishes the seed for the garden or makes some allowance for it.

Q. (By Mr. A. L. HARRIS.) Have you any foreign immigrants in your section of the country?—A. Very few in my county. One township of the county, which is called German Township, was settled by Germans and French nearly altogether. They were all foreigners originally, but they have lived there for many years, and of course their children are American born. Some Polanders went there to work on railroads, and some few of them have bought farms. In our immediate section the people are mostly native Americans.

Q. What is their percentage of illiteracy compared with the American farmers?—A. The German families that come there are usually pretty well educated; sometimes better than Americans. Of late years the farmers are taking more interest in the schools and send their children to them.

Q. Is there any tendency to colonize?—A. Yes, among the Germans and French there is. They generally all go into that one township. They pay almost any price for land there rather than go outside. A great many belong to the same church and go together. They will not be separated. There is, however, not a great deal of that in our section. It is mostly west and north of us.

Q. Is there any tendency to preserve their foreign customs and language?—A. There is some; yes, sir. Some insist upon having German and French taught in the district schools, and they talk it in their families. But a large majority of them are growing away from that, preferring that their children shall be educated in English, knowing that they are going to make this country their home.

Q. What is the effect of this foreign immigration on agriculture?—A. It has damaged the farmers of the Eastern and Middle States to open these territories in advance of the world's needs.

Q. Are you speaking of the country at large?—A. Oh, yes. We have suffered materially. What has hurt agriculture in New England is the agriculture west of New England. What has made low prices in Ohio for agricultural products, is the fact that these large areas of land have been brought under cultivation in advance of the necessities of the world.

Q. What suggestions have you to make in regard to the regulation of immigration?—A. I have changed my views somewhat upon that. I used to think it was a grand thing to have all this country settled up, but I think the time has come

when we realize that it would have been better for us not to have encouraged immigration. At least there should have been restrictions. I would require that they bring something with them to show that they have been prudent and industrious persons. I would require some educational and moral qualifications. I would be very sure to insist upon the moral qualifications, in order to shut out the dangerous classes that they want to get rid of abroad. Of course I am speaking of it from the standpoint of the interest of our people here. It seems to me that it would have been better for our people to have gone a little slower. I think we were altogether too liberal with our lands. We might better have held them until the world really needed the products of those farms. When I saw the train loads of emigrants going West years ago over these trunk lines, I said to the farmers: "We will sometime hear from these people in the markets of the world."

Q. (By Mr. FARQUHAR.) Are you speaking of the undesirable element in that immigration?—A. Oh, yes; yes. Of course, I would not close the door in the face of good people that come here to become good citizens. The point I wish to make is, that if we had it to do over again it would be better not to make it so much of an object. I would not advertise our free land so extensively; I would not invite and urge them to come, as our people did. I think we made a mistake in giving the railroads the quantity of land we did, and the homestead law was carried to extremes in giving away the public land. A great many people that went there did not get the advantages they hoped for. The large increase in production brought down the prices of agricultural products below the limit of profitable production. There was no profit for them, and it glutted our market to our great loss. Of course this land would have all come under cultivation in time, but it ought to have come naturally. If the settlement of the Northwest had been a natural settlement, a natural pushing on there by the pioneers, as it used to be when this country was developed and settled, there would yet be an acreage of land left there for our children. Now it is all taken up.

Q. Were not the railway companies anxious to have the farms settled in order to give them local traffic, especially along the roads that pushed West to the Pacific coast?—A. Yes, sir; it was good for the railroads, but not so good for farmers of the Middle and Eastern States.

Q. Do you think the disadvantage of the Eastern and Middle State farmer is on an increasing grade or has it come to a stop?—A. I think the reaction has set in. I think a farmer will do better to go East than West now, but there has been a time when it was the other way.

Q. Has the diversification of crops by the Middle State and Eastern farmer given him a wider market for a smaller class of products and a class easier produced, than the Western man can possibly bring into the market?—A. He has had to change his system of farming entirely. This has been an advantage to some of them, depending a good deal upon location. It has been particularly hard on the farmer in the East who is far from some center of population.

Q. (By Mr. KENNEDY.) Was most of the inviting of immigrants you speak of by the foreign steamship companies that profited by immigration?—A. The foreign steamship companies and the railroads. The railroads that had this land to sell of course wanted the homesteads taken up to enhance the value of their land.

Q. Does most of the undesirable immigration that comes to this country remain in the cities, while the really desirable immigration goes to the farms of the Northwest?—A. Largely true, no doubt. The most desirable class usually go to the farms; the undesirable class does not usually go out on the farms; they can not stay on the farm without becoming pretty good people.

Q. (By Mr. FARQUHAR.) Is it impossible to get them on the farm?—A. They are clannish and not satisfied to go on the farm. A good many of them, if they knew how to farm, would go out into the country. Many of them have a very hard life in the mines and elsewhere, and would do much better to go on to the farms.

Q. (By Mr. A. L. HARRIS.) What is the school age of children in your State?—A. From 6 to 21 in the public schools.

Q. What have you say in regard to the sufficiency of the public-school facilities?—A. We are well provided in Ohio with good schools.

Q. About what size are your districts, through the country, as a rule?—A. I think 2 miles square or thereabouts.

Q. What is the character of the schoolhouses?—A. Good schoolhouses; fine schools.

Q. And the teachers?—A. Good teachers and good schools; we are ahead of the East now, as far as the district schools are concerned.

Q. Can you state what per cent of the school population is enrolled in the

schools?—A. I have not the figures to give you the exact per cent, but in the country districts it is a very unusual thing for the children not to attend the district schools. The young children usually go 6 months in a year, and when they get older and can work perhaps they stay out of school in the summer and go in the winter. But of course there are families that do not send their children unless compelled to do so, but they are very scarce, and a man would hardly be permitted to stay in the community now if he would not let his children go to school.

Q. (By Mr. CONGER.) Do you mean for the entire period of the school age you just mentioned, from 6 to 21 years?—No; I mean they start in at 6 and go summer and winter until they get old enough to work. They are hardly ever taken out of the summer school before they are 10 or 12 years old. When a boy gets stout enough, about 13 or 14 years old, he usually helps his father on the farm in the summer.

Q. Until about what age do the boys continue in school during the winter?—A. If they want to get just enough education to enable them to do ordinary work they will quit going at about 16 or 18 years of age. Others will, if they desire an education after they reach that age, generally go to a higher school.

Q. (By Mr. A. L. HARRIS.) Have you a provision in Ohio for a township high school?—A. Yes, sir; I think we have it in some sections; it is not very general in our State.

Q. (By Mr. RATCHFORD.) Do you believe that compulsory education should be enforced in the agricultural districts?—A. I think most of the farmers that have boys have a desire to give them an education. I think they almost always give them all the advantages that are within their reach. If they do not send them away from home and hire their board, they give them all the advantages they can get near-by. Some boys and girls fritter away their time in school and then the farmer thinks they will be better educated if they are put to work. I do not know of any farmer who would not rather encourage his boy to know more, although he might probably ask him to stay home in the busy season in the summer and take the 6 months in the fall or winter.

Q. (By Mr. A. L. HARRIS.) What have you to say in regard to the adaptation of the public-school course in your State to the needs of the agricultural people?—A. I think that the elementary principles of agriculture ought to be taught in all those schools. Of course they would not go into it extensively, but they ought to know something about the soil, how to maintain its fertility, etc., and what kind of farming will pay best in particular localities; all the things that a farmer ought to know to succeed on the farm.

Q. (By Mr. FARQUHAR.) Would you advise including the chemistry of farming in these schools?—A. I do not know that I would very extensively in the district school; I would go into it somewhat, however. Their minds ought to be impressed with the importance of maintaining and not exhausting the fertility of the soil. There are certain kinds of farming which exhaust the soil in a few years, and there are other systems which are not so exhausting. They ought to understand that it is not economy to feed all corn, for it is not a complete ration, and I would like to see such information furnished in county schools. A great many boys who leave the farm would stay and become interested in farming if there was a little elementary instruction in that line. I think every man ought to be taught to earn his living with his hands. Farming is one of the surest methods of getting a living.

Q. Do you think the increased knowledge of the American farmer during the last 30 or 35 years in respect to soils and the feeding of stock has doubled the ability and the capacities of most of them?—A. It has increased it very much. Of course, there has been a great improvement. Farmers now try to avoid the exhausting of soil. They are trying now to restore and maintain the fertility. They are making great progress in that direction. That has been one of the things we have kept constantly before the farmers in our organization.

Q. Has the United States Agricultural Department done an immense amount of good?—A. Undoubtedly it has done much good in increasing agricultural intelligence.

Q. Do the young men usually take to the agricultural college and the experiment station?—A. No; the larger share of the young men that want to get an education do not go to the agricultural and mechanical colleges. They want an education in the hope of engaging in some other work. Of course, it is getting better. The number of farmers' sons that feel that way now is decreasing rapidly, but a great many farmers thought if their boys were to be educated they did not want them to come back to the farm; but there has been a wonderful change in that during late years.

Q. Do you think it would be better to have agricultural education a part of an established college than in a separate college?—A. No; I want the agricultural college by itself; I want it separate and distinct. These attachments to the regular universities are humbugs, as a rule. They get money of the people, appropriated for giving instruction in agricultural and mechanical arts and then teach the classics.

Q. I would like to hear you explain that in a practical way.—A. They want the money. They are greedy for that always, and they think they can get the money and put off the farmer with little return for it. And so far they have been able to do it. I understand that in many States the universities have simply robbed not only the farmers, but the mechanics. I can remember very well when in Ohio our agricultural college had just one professor to give instruction in agriculture. All the rest of the money was going in other directions. There are many colleges in the country now that give very little instruction in agricultural and mechanical arts, but they get the money. The best condition possible for an agricultural college is to be an agricultural and mechanical college, an industrial institution where the sentiment is that it is honorable to work at any honorable employment. That is what you want with the boys who are getting an industrial education. You do not want them to be influenced by anything in the air that would indicate that a preacher or a lawyer is more respectable than a farmer or mechanic or any better. That is my idea of it. There must be a spirit of pride and enthusiasm. Of course there are a good many of these institutions that have got other educational advantages aside from agricultural and mechanical, that are doing very good work. Our organization has made it a point to make the fight on that line, and we have accomplished quite a little. A few years ago there was a bill pending here to give more money to the agricultural colleges. There was no provision that it should be expended in giving instruction in agriculture and the mechanical arts. Our organization went before the committee and said, "You must put into that bill a provision that this money shall be expended only in giving instruction in such branches as pertain to agriculture and the mechanical arts." We had quite a fight over it, but they did it and saved the bill. In some places it is carried out in good faith, and in others it is not.

Q. (By Mr. A. L. HARRIS.) What is the total capital employed in agricultural pursuits?—A. I have the exact figures, but not here. A little over \$15,000,000,000.

Q. What are the comparative earnings of that occupation at present compared, say, with 40 years ago?—A. I think farmers made more 40 years ago on a given amount of money invested in a farm than they would make to-day.

Q. Will you please state the reason for that?—A. The valuations of property were lower then, averaging the country over. In some localities they were higher than they are now, but through Ohio 40 years ago land was not valued as high as it is now. He would have more land and probably for the same amount of money could get more live stock. Labor was much cheaper, and he depended very largely upon the local markets. He was not affected quite so much by the competition of labor all over the world engaged in agricultural pursuits. I think he had more left of real profit out of his investment then than he does now. Of course, there is a good deal of guesswork about this, and I would have to investigate before being too sure of it. You know, a man that was worth \$10,000 was a rich man 40 years ago, or a little more than 40. He was called very well off, and I remember very well when a man worth \$5,000 was considered a rich man in Medina County, where I lived.

Q. What was the difference in the purchasing value of a dollar then and now?—A. A dollar will buy a good deal more now of most things than it would then; of clothing, furniture, and everything of that kind.

Q. (By Mr. CONGER.) Will it buy as much land?—A. No; it will not buy as much land and it will not buy as many cattle. He would not have to invest as much then to make the same amount of money. He would probably realize as much advance on a steer then as he would realize now, and he would have a great deal less capital invested in the steer. His taxes were very much lower.

Q. (By Mr. KENNEDY.) If he would go to town now with \$5 or \$10 would he bring home nearly twice as much sugar, calico, and so on, as he could then?—A. And almost everything. I can remember when farm tools cost, perhaps, twice as much as they cost now. Perhaps a plow might be an exception. Plows are about as high now as they were then but they are better; but take the small tools, hoes and pitchforks, and you can buy just as good for 80 cents now as you could then for \$1.

Q. Would he bring home a better character of plow or cultivator now?—A. Very much, and \$1 will buy more of almost everything of that kind. Sometimes

some of the things we buy to-day do not wear as well as some of the old-fashioned things.

Q. (By Mr. A. L. HARRIS.) What are the earnings of the capital invested in agriculture compared with other lines of investment, such as banking, manufacturing, mercantile business, and railroading?—A. In a general way they are one-third or one-half less, as nearly as I can figure it out. Take all the capital a man has invested in farming and figure the per cent he is getting, and it will, perhaps, range from 2 to 3 per cent. There may be some instances where he would realize a good deal more than that and others where it would not be as large. I do not think the net profit would range much above 3 per cent.

Q. Do you mean after the living is taken out?—A. I mean the net profit, after you had credited the farm with your living and charged for work, etc.; charge all you pay out and credit all you take in. Now, of course, that is my idea; take the country over, 2 or 3 per cent, perhaps, would be somewhere near it.

Q. What have you to say in regard to the taxation of agricultural property as compared with other industries?—A. My impression is that agricultural property pays more than its proportion of the taxes.

Q. Will you state how?—A. In the first place, it is all visible property; you can not hide it. I am speaking of farm property; I am not speaking of those farmers that may have some money invested in stocks, bonds, etc., but I mean the land and the cattle and the tools and the grain. The assessor finds it all; he comes around and gets all of it. He has a long list of questions that it takes an awfully shrewd farmer to dodge in returning the property, and then he has to hold up his hand and swear to it. They do not ask the city fellows to swear; the assessor does not require it. The assessor knows what farm property is worth. If you have a good horse he knows about what it is worth; they do not pretend to put it in at 100 cents on the dollar of its value, what you would take for it. Farm property goes in from 40 to 75 per cent of what the owner would consider it worth to sell; that is the way it goes in for taxation. Do you want me to go on a little? In the first place take the real estate, and you know how it is valued in our State. It is appraised once in 10 years. When a land assessor is to be elected the people in town are pretty sure to get some shrewd fellow who is expected to favor town property. I am speaking of Ohio. They may put the land in at a pretty fair figure and the buildings pretty low on the farms, and then when they come to the town they put in the buildings low where the principal value is in the buildings. And the farm that would rent at a fair rent for say, \$250 a year, will pay more taxes than a business block that rents for \$500. Of course the large corporations and large interests manage to get their valuations down pretty low.

When it comes to personal property, after they get through with the farmer they come to the merchant. The law requires that this property shall be returned at its actual cash value. The merchant says: "The farmer puts in his property at 40 to 60 per cent; he does not give the value, and it is not fair that I should put in my property at full value." The law requires him to put in the monthly average value of his stock; that is the law in Ohio now. The question is, How much shall he return? He averages up all through the year. There was one farmer who sold his farm and went into merchandising, and he took an inventory and divided his inventory by twelve and returned the quotient. He thought that was about the fair way to return it, and that is about the way our mercantile friends return it in Ohio.

Q. (By Mr. FARQUHAR.) Does that valuation stand with the assessor?—A. I think it does generally.

Q. Was that farmer a granger?—A. He was a farmer and he left the grange when he went into merchandising. Of course, he had a different way of getting at it than the other fellows, but the other fellows reached about the same result. The merchant that will carry about \$25,000 worth of stock will advertise it for sale on that basis and returns it for taxes at \$2,500, and lots of them carry \$10,000 stock and return them for \$1,000. I can show you a merchant in an adjoining county that carried \$25,000 of stock and only returned \$1,000. The merchant will say, "It is not right; I know it is not right, but the other fellows are putting it in about that way and we do about as they do." So much for merchandising. Then come to the man who has notes and mortgages and makes his living out of the interest and buying and selling. I don't care whether he is a farmer or who he is. But it is astonishing how poor those people are. When an assessor comes around, they have very little to return for taxation. Then, go to the local banker and it is astonishing how much business he can do on a capital of \$1,000 or \$2,000. Some of the strongest banks in Columbus, if you recollect, Governor Foraker said in his message had their valuation at less than \$2,000. The manufacturers

in Ohio for years made no return on goods that had been carried over. His factories, his buildings, and his warehouses could be full of binders, wagons, and carriages, and not a cent was returned for taxation on that property. If one of them would be sold to a farmer it would be returned and he was taxed on it. That was the law, they were shrewd enough to get that little provision into the law that we grangers struck out a few years ago; and of course it made the amount they returned according to the property they had, very low. Take the State over and I will guarantee that the merchandise of the State of Ohio is not returned for taxation at over 15 per cent of its value; I think that is a proper estimate; while farm property will run from 40 to 50 per cent. Outside of the national banks, where you can get at them, bank property has not returned that much; the men that own notes and mortgages, take the State over, had not returned 15 per cent of them. A great deal of this property seems to be out of the State when the assessor calls. Some fellow takes a mortgage in his own name but does not own it; and it is very hard to find it until after the assessment is over. So that, taking it all in all, the farmer pays more than his proportion, not because he is more honest than other men, but he can not secrete his property. I do not know that he would but he might; there are some farmers, no doubt, that would. We do not ask the merchant what his stock inventoried at the last inventory, but if they would just give us an inventory at the lowest point in the year they would pay a great deal more taxes; they would come somewhere near paying their proportion. And there is a way of getting at these bonds, mortgages, notes, etc., but they do not get at them, and for that reason the farmer pays more than his fair proportion.

Q. (By Mr. KENNEDY.) What per cent do farmers have to pay for money at the local banks?—A. That depends a little upon the locality; they can get it from 5 to 8 per cent I think.

Q. How can they do that without being ruined if they make but 3 per cent on their invested capital?—A. They are very apt to go that way if they borrow too much of it. A man can borrow a little to bridge over and pay it off.

Q. Is there much borrowing done at the banks?—A. No farmer to-day borrows money if he can possibly help it. They used to borrow liberally, and they did not think it was worth while to pay if they saw a place to put the money and make more out of it than the interest; but the experience of the last few years has taught the farmer that he never should borrow money unless he knows whence the money is coming to pay his debt. No farmer worthy of the name of farmer will borrow money unless it is to make some shift. If he has some stuff to ship, perhaps he will borrow the money to ship his stuff and sell it and pay it back. If the farmer sees something he would like and does not have the ready money, he will not borrow it; he does not borrow unless he sees where the money is coming from to pay it back.

Q. (By Mr. A. L. HARRIS.) What effect has the decline in the value of real estate since 1866 had on the valuation for taxation?—A. It has not declined for taxation as much as in actual selling value.

Q. Now, there is a constant decline in the money value of the farm; would the farmer have to pay the tax pretty nearly on the full value of the farm?—A. He gets no rebate from that; the appraisement is for 10 years. He has to pay on the appraiser's value. But all farms have not declined; good farms that have been taken good care of have not declined in value materially.

Q. I have heard it said that farm land has decreased from 50 to 100 per cent. Is that true?—A. That is not so. There may be a few localities where they may have done so.

Q. (By Mr. RATCHFORD.) Is there a board of equalization in every county in Ohio?—A. Yes.

Q. If a man can show that board that he is taxed unjustly, will he get a reduction?—A. If he can show them that his property has been appraised at a higher valuation than the same kind of property of his neighbor he can have that equalized; but he could not receive relief by going before that board and showing that the merchant has returned merchandise at less than his own property is returned. They can equalize land values only once in 10 years. When the township appraisers have done their work the county board takes the matter up and equalizes the valuations in the county between individuals, and then it goes up to the State board of equalization and the State board takes the matter up and equalizes between counties.

Q. (By Mr. FARQUHAR.) Is your county board given the authority of spreading the taxes within its own county lines?—A. They can equalize it between individuals within their territory; they can take it off of one and put it on another.

Q. (By Mr. A. L. HARRIS.) What would be done in case of a building being burned and a new building being erected?—A. The new building is put on, I suppose. If a building is burned it is taken off, I presume.

Q. (By Mr. RATCHFORD.) Is it your observation that the farmer is burdened with taxation compared with the workingman who owns a home in the city?—A. I think farm property is in at a higher per cent of its actual value. Of course, there are exceptions, but I think that as a general rule the town property, the real estate, including the buildings, is put in at a lower rate. In other words, if a farm would sell for \$5,000, property in town that would sell for \$8,000 would pay about the same taxes as the farm would.

Q. Do you think, on the whole, that the farm property is at a disadvantage as compared with all city property in the matter of taxation?—A. I think that in making up the valuation of property the people that live in town watch the matter more closely. Of course, a great many do not have anything to do with it, but there are shrewd men who have a great deal of money invested; and they see that some man is put on to value the property who will, at least, be very fair to their city. They control it.

Q. Is that also true of the country districts?—A. Where it is all in the country they try to get a man who will return it low enough. If it is lower than the neighboring township, it is raised. But generally the same man assesses the property in the town and country, and I suggested the idea, perhaps, that they put the land in as high as it ought to be and the buildings low on the farms—that is, it seemed low—and when you come to the town, where the principal value is in the buildings, they are put in low. This applies to small towns or villages.

Q. (By Mr. FARQUHAR.) Do you mean the assessor is more susceptible to the town influence than to the country?—A. Yes, sir.

Q. Are you so scattered you can not select them?—A. We neglect our duty. At the last valuation, however, we took off a good many millions from the farmers and put them on the cities, and yet we did not get it equalized.

Q. (By Mr. RATCHFORD.) Did you do that through organization?—A. Certainly; no other way in the world.

Q. (By Mr. A. L. HARRIS.) Are the tax methods in Indiana very much like those of Ohio?—A. Indiana is very much like our State.

Q. Are there any other States that are collecting more on the railroads than Ohio?—A. The valuations on the main lines of railways in Indiana are about double what they are in Ohio. The side lines are about the same—that is, the extra track, if they have a double track.

Speaking of taxation: A business block in town that will rent readily for \$500 a year will not pay as much tax as the farm outside that rents for \$250. Of course there are individual exceptions. That is the rule. I am not finding fault with these conditions—simply stating what I regard as facts.

Q. Have you any suggestions to make now as to the unification of tax methods, providing it could be accomplished throughout the States?—A. I think the law should apply everywhere. I think when you go into the details and ask the farmer to return the number of his horses and cattle, and his hogs, and the number of bushels of corn, and everything, when you go to a man who has other kinds of property, he should list it by the piece, just the same—make a full exhibit; and if the farmer is required to swear, he should be. Valuation of property for taxation should depend somewhat upon its productive power. Sometimes there has been a great deal of money invested in a plant, for instance, that has ceased to be valuable; it should be appraised at what it is actually worth; that should be the basis, and every man should pay his fair proportion.

Q. Do you know of any States in the Union that raise almost their entire revenue from corporations—railroads?—A. Pennsylvania's State taxation is all from the railways, I think, or from corporations. There is no direct tax, I think, on land at all in Pennsylvania for State purposes.

Q. Would you suggest that there should be a unification, at least so far as taxation of corporations is concerned?—A. I think it should be uniform, so that they would not dodge from one State to another to escape taxation. People who actually live in Ohio, and own property there, go to New York or some other place a part of the year, where they can get rid of taxation. If there was uniform taxation all over the country they would not do that.

Q. (By Mr. CONGER.) I understood you to state that the largest private banks of Columbus were appraised at from \$1,000 to \$2,000 each. Is that also true of the national banks?—A. No; they get at the stock of the national banks. I would not say here that that amount is returned by those banks now. I do not know whether that is true now or not. I simply referred to the fact being stated in the message of the governor to the legislature some years ago. The banks never denied it, and never forgave him, either.

Q. (By Mr. A. L. HARRIS.) Do you know whether the national banks are assessed at the full value of their capital stock?—A. I do not think they are. I think a few cases were tried in court where they claimed they were paying more than other kinds of property, and the courts decided they could not be made to do so, and their property was returned for taxation at the same value as property around them.

Q. Please state what has been the decline in prices of agricultural products in the last 30 years?—A. I think the prices are somewhat lower than they were 30 years ago, taking the general average. Of course, some things are higher and some lower. I think the general average has declined. I mean by the same measure of value. Thirty years ago we were not on the same basis as we are now.

Q. What has been the decline in the money value of agricultural lands in your section?—A. In my immediate section there has not been very much decline, if any. In some sections of the State there has been quite a marked decline. In the older sections, where they have not kept up their farms, exhausted the fertility, let them run down, and the buildings and fences have run down, there has been quite a marked decline. My part of the State is a new country. The soil is rich and has been drained and improved, and I suppose there has not been very much decline there. Good farming land ranges anywhere from fifty to eighty dollars an acre in that section.

Q. What has been the decline in the productive power of the soil?—A. There has been a marked decline in that. It is in counties where they must use fertilizer to get a crop, and if they do not use fertilizer they do not get crops. They have drawn on the soil until it is largely exhausted.

Q. Where the soil has been exhausted, you think that is one of the causes of the decline of the value of the land?—A. That is one cause. There are other causes, but that is the principal one.

Q. (By Mr. FARQUHAR.) Do you help that by diversification of your crops?—A. Yes; rotation.

Q. And by resting the land or fallowing?—A. We do not fallow in Ohio any more; we fertilize it and keep more stock.

Q. (By Mr. A. L. HARRIS.) What has been the increase of acreage under cultivation in your State in the last 20 years?—A. There has been some increase; not very much in our section.

Q. What has been the increase in the country at large?—A. I do not think that there has been any increase in the Eastern portion. There has been rather a decrease. In the West there has probably been an increase—that is, new lands have been brought under the plow; and you may take some sections in Ohio, through Madison and Ross and the Sciota Valley, where they used to raise a great many cattle, they are plowing more and raising more corn and wheat.

Q. What has been the effect of this increase in acreage of farm land for cultivation on production and on prices?—A. It has very largely increased production and of course has lowered prices. The opening up of this great expanse of country in the West, bringing into competition with the other farms millions of acres that were not cultivated a few years ago, has had a marked effect on prices. The prices of agricultural products depend upon the amount produced. The demand is about the same all the time. If you have a very large production, you get very low prices. A very unusual crop for a series of years makes a farmer poor. For instance, the four largest crops of corn we ever grew in this country were worth \$233,000,000 less than the four smallest crops we grew in the past 20 years. The four largest crops of potatoes were worth \$70,000,000 less than the four smallest crops in 20 years. In other words, if you offer the consumer more than he wants to buy, he fixes the price and fixes it low.

Q. (By Mr. RATCHFORD.) The farmer does not always sustain the loss that people usually believe he does by reason of shortness of crops?—A. No. A medium short crop is usually better for the farmer than a large crop. The individual farmer, if he raises big crops, makes money; but when farmers all over the world get very large crops the price is so low it leaves no profit. Two years ago you could not sell the best apples for 75 cents a barrel; this year you get \$5 a barrel. For a long time the price of corn remained pretty well up, but the continuance of the big crops finally broke it down.

Q. (By Mr. A. L. HARRIS.) What has been the effect of bonanza farming as practiced in the West upon the smaller farms in the East?—A. It does not hurt us a bit. They are the fellows who lose money. It is the men who went up there who had wives and children big enough to pick up potatoes and work all day long who hurt us. It is not the bonanza farmer. Those people are breaking up; they are not going to hurt us any more, if they have ever done it; they do not hurt us now.

Q. (By Mr. CONGER.) Did not the farmers of Ohio in former years raise considerable wheat?—A. They do now; it is one of their main crops.

Q. Is it not the bonanza farming that brought about the very large crops of wheat that have been produced in this country?—A. Of course they have contributed to the large crops. I do not think they have hurt us very much. If all that country up there was in the hands of bonanza farmers, and those other fellows were in Europe, where they were, eating our farm products for us, I think it would be better.

Q. (By Mr. FARQUHAR.) Do you think the consumer should be on the other side of the Atlantic?—A. No; but if he is a consumer over there he won't hurt us so much as the producer here. I think there has been a time, of course, when that bonanza farming has hurt us, but it soon reaches a point where it does not amount to much. They exhaust the soil, and it is expensive to keep it up. The soil is becoming impoverished; they take out the fertility; it is all taken out, and nothing is put back. That has not hurt us except along with the other kind of farming. The vast increase of production has affected prices. That method of farming—tilling the soil—has not injured us more than the ordinary style. We can hold our own with them, I think, pretty well. Of course we grow wheat in Ohio in a rotation of crops. It is not a specially money-making crop. Wheat is all they have up there. Perhaps you have a wrong impression. I did not mean the increased production did not affect the price of wheat. I do not think that style of farming hurts the farmer more than he would be hurt if the land were divided up into smaller farms.

Mr. JONES (president of the National Grange, who was present to give his testimony). There is a difference between bonanza grain growing, which is impracticable, and bonanza stock growing. There are bonanza stock growers who handle sheep, hogs, horses, and cattle, and I think they do injury to the farmers in the Central States. I think this bonanza farming should be defined, in order that Mr. Brigham may not be misunderstood.

A. (Mr. BRIGHAM, resuming.) I do not agree with my friend Jones. I do not think that competing cattle raising is hurting us. I will let him testify as to that. I think when they sum up their losses they will not find much profit. I think we are hurt by the men who control the prices in Chicago.
